FIG. 5—FIRST OPERATION ON LARGE SPINDLE.

the end, a three point roller steady is brought into position, whilst a 3⅝ inch diameter inserted cutter drill is used. The feed of this drill is about ½ inch a minute. Other tools in the square turret are used for undercutting for grinding, and for turning and facing the flange.

The hole is not drilled right through at the first operation, and at the second, the work is gripped on the flange in soft jaws, the reduced diameter going into the spindle, where it is steadied by a bush fitting in the spindle bore. The second operation consists of drilling to meet the hole produced at the first operation, and facing. The time for the first operation is about 1¾ hours, and for the second operation three-quarters of an hour. During the two operations about 220 pounds of metal are removed.

Whilst on the subject of machining forgings, it will not be out of place to draw attention to a point which must be observed in turning forgings with the roller steady boxtool or roller steady turner. Tools of this kind cannot be brought straight on to a rough forging without a preliminary truing operation. In dealing with the spindle you possibly have observed that the roller steady turner was given a true start by having the end of the spindle turned up a short distance with a combination tool which came on to the work just after the starting drill. This is quite satisfactory where the work has a hole, but in the case of a solid article, other means have to be adopted.

### Some Special Tools

Having considered some representative lay-outs, we will next take one or two examples of quite special tools which deal with the unusual operations. The next photograph, Fig. 6, shows an arrangement used for machining spoked hand wheels for operating machine tool slides. By means of this lay-out, practically the whole of the machining is completed at one operation in very good time. The casting was held on a special fixture, being gripped between two plates under the rim. Before tightening up the three nuts, the boss is located central by bringing up a cup centre carried on the turret. The drilling, boring and reaming of the boss are straightforward operations, but for turning the radius on the rim a very interesting tool is made use of.

This machining is done with a cutter in a tool post carried at the end of a swivelling arm, fitted to a spindle mounted in a bracket on the back of the cross slide. The spindle is made to revolve by means of a pinion cut solid with it, and operated by rack teeth cut on a round bar extending from the combination tool. The cross slide is brought forward to a stop, the rack engaged with the pinion, and the automatic movement of the turret slide then imparts the feed to the tool. At the end of the forward travel, a chamfering tool finishes the edge of the rim. When not in position, the rack is carried round by the turret like a boring bar. This hand wheel is 9 inches diameter and is finished in 9½ minutes.

The method of profiling by using a cross sliding tool mounted on the turret and guided by a former on the cross slide has been described in connection with the pump body job, and an elaboration of this occurs in one of the operations on the "Le Rhone" aero-engine crankcase. The internal surface of this is spherical, and, owing to the fact that it is interrupted by the holes for the cylinders, must be machined by a single point traversing tool. The tool employed is shown in position at Fig. 7. The tool holder is lipped to provide a good support for the tool, and the moving slide has an additional support on a square swivelling block carried on the pilot bar, which fits a machined slot in the front slide. In this case you will notice that the former in the square turret is double sided; in other words, it is a curved slot in which the guiding pin travels to determine the path of the cutting tool. The reason for making this former double-sided was due to a certain amount of apprehension on the part of the tool designer, who considered that there was a possibility of the tool being dragged by the top rake into one of the cylinder holes, with a consequent nasty smash. Whether this danger was a real one is a debatable point, but the method of making the former double-sided certainly avoided the risk.

In considering these various lay-outs which have been presented, you will notice the large extent to which the standard tools are used, and the difficulty in getting good results from capstan and turret lathes is now much less than formerly, since makers of this class of lathe are in a position to furnish standard tool outfits of wide general utility, which reduce the outlay on special equipment to a minimum. Despite this, the necessity for special tools will always exist, and the ingenuity of the designer will be taxed to meet special conditions. The time has undoubtedly come when it is appreciated that turret lathe tool design and practice is a subject which is worth all the attention which can be given to it, and that the tool designing and planning engineer has a big place in the scheme of production. The success of any lay-out or combination of tools is dependent on the sound judgment of the designer, and this, in turn, can only be based on past experience and familiarity with the best shop practice.

## MACHINING A LARGE GEAR BLANK

(Continued from page 74)

the feeding and chucking can be said to be semi-automatic, while the other movements still remain fully automatic.

Where there are no threads to cut a plain machine will perform all the other operations possible on the standard type with the exception of threading, and other operations when the stock is held stationary, such as cross-drilling, slabbing, slotting, milling from the side, etc. A plain machine is usually found ideal on such work as rollers, pins, bushings, washer work, and such like parts.

Where the parts are very simple, two or three pieces can be completed at once, in other words eight or twelve pieces can be in process at one time, two or three to each bar. From this it will be readily seen that the quantity possible to be produced on such machines is very largely dependent upon the man in charge. If he is up to date and anxious to increase his production, he will study his tooling, improve it where he can, use auxiliary attachments wherever possible, and in every way try to keep his machines running to full capacity. Two operators running a battery of similar machines might secure very different results.

# The Need of Medical Service in an Industrial Plant

## The Idea is to Keep Men on the Job by Doing Away With Needless Time Losses by Reason of Neglecting Injuries—How the Idea of Safety is Being Taught

ABOUT six months ago the Massey-Harris Co. started a movement to extend the system of first aid and safety work they had been doing, and as a result they have today a much more complete medical service than they have ever attempted in the past. Dr. H. W. Baker is in charge of the medical department, spending nearly all of his time at the Toronto works. At the Weston works an experienced first aid man is in charge. At Brantford they maintain a service by a local doctor, E. A. Smith, M.B., who is at the works each day from 9.30 to 11.30. A graduate nurse and a secretary are also on the staff at Brantford, while a graduate nurse does first aid work and keeps statistics at the Verity Plow Co. in the same city. A medical officer also devotes part of his time to the work at the Bain Wagon Co., in Woodstock.

An official of the company, speaking of the work undertaken along these lines, stated that: With the reorganization, we have taken the view more strongly than ever that this is not a charity work but a good business proposition by which the employee and employer benefit. We taboo the word "welfare" because it savors of charity. We are here to give service to the employee and to do all in our power to make him more satisfied with his job.

We have established a department in each of the five factories, with a staff as charted in Fig. 1.

At the Toronto works, with about 2,000 employees, we have five rooms.

1. A small waiting room, small because it is our policy to have no one kept waiting.

2. A ward equipped with two beds and a couch. This room is used for men when they become ill or in cases where we are waiting for the ambulance to transfer them to the hospital.

3. An operating room. This is a room 14 feet x 18 feet, well lighted by six southern windows. Four electric lights for dark days do away with all shadows. This room is equipped to do all emergency work. We have two chairs raised seven or eight inches from the floor, with a glass covered arm where all hand dressings are done. Foot rests can be pulled out in front of these chairs where foot dressings can be done. Between these two chairs is a dressing drum with four compartments holding four different styles of sterile dressings. There is also a small instrument sterilizer and dressing table containing solutions and bandages. Above our wash-up basins we have a small tap from our gasoline supply which is used to remove dirt from injured hands. There is a foot bath for treatment of contusions of the feet and a cabinet for our instruments. Along one side of the room there is a cabinet 18 inches deep extending from the floor to the ceiling and equipped with sliding doors. This is quite sufficient for all supplies.

Staff of Medical Department at Massey-Harris Toronto Plant. Left to right: Miss Dempster, Miss Cooper, Dr. Baker, Miss Hill, Miss Edwards.

In one corner we have a revolving chair and an adjustable lamp for eye cases, a shelf of the cabinet at one side being equipped with all material necessary for this form of accident. A 20th Century eye test box is installed in one corner of the room with equipment 20 feet distant for the moving of the letters.

There is an alcove in one corner about five feet square for the secretary. A filing cabinet for records, a desk with typewriter, a cabinet for sorting the records into their departments and two telephones are within easy reach of the secretary's chair.

4. The laboratory is a room 5 feet x 12 feet, completely equipped for all the laboratory work that is necessary to be done. A water centrifuge, an electric incubator, a microscope, bunsen burners and other paraphernalia are conveniently arranged. In this room we have our drug cabinet and large dressing sterilizer.

5. Medical director's office. This is a room 10 feet x 18 feet and is equipped for making physical examinations of employees. There are two curtained cubicles, 3 feet square, an examining table, scales and a wash basin.

These rooms have a terrazo floor and in the operating room this has rounded corners to facilitate cleaning.

At Weston Works (tractor plant) with 200 employees, the timekeeper is a well-trained first aid man. This plant is just nine miles from Toronto works. It can be easily reached by street car, therefore, our first aid man takes no chances, an accident case, when necessary, being

Operating Room in Massey-Harris Toronto Works. Views show how the room can be adapted to treating various kinds of injuries. It is well lighted at all times, so doctors and nurses work under the best conditions.

sent to the Toronto Works medical department by automobile or street car. The medical director visits this plant each week or oftener if necessary .

At our Brantford works, where there are about 1,000 employees, we have had a nurse on duty for about two and a half years. There is a well equipped operating room which, until the recent reorganization, was sufficient. With the recent addition to our staff of a part-time medical officer and stenographer, we have acquired more room.

In one corner of the operating room a bed for emergency cases is screened off, the stenographer with her records is established in another corner. The medical officer, who puts in two hours a day at this plant, has his desk in another room where he does his consulting and makes his physical examinations.

Our graduate nurse of this plant has so won the confidence of the employees that she has increased the attendance from a dozen a day to six times that number.

At the Verity Plow Company, Brantford, with 500 employees, there has been a nurse on duty for over one year. The operating room here is also well equipped for all emergencies. At present we have no medical officers in this plant, but there is a doctor quite convenient who is called for emergency cases.

At the Bain Wagon Works, Woodstock, with about 300 employees, there is a medical officer who comes to the plant for one and a half hours three times a week for consultation. The rest of the time he is on call for emergency cases. The fire chief is a well trained first aid man who has remarkable ability in judging whether or not a case is serious enough to be sent to a doctor.

### Treat Cases Quickly

We give first aid and follow-up treatment to all accidents and we call even a scratch an accident. We classify these cases into major and minor, calling major all cases that the doctor should see or those that lose any time whatever. The accident cases are the only ones which the doctor goes outside the plant to see, these patients being attended to at their homes or in the hospitals if necessary.

Some of the simplest accidents that have happened in our works have turned out to be the most serious because of blood-poisoning. This condition can be prevented by prompt and efficient treatment of each and every wound that is deep enough to show blood. Therefore, we urge every employee to come for a dressing immediately upon receiving an injury. Last month no case treated within an hour of the accident became infected, but we had ten who came to us for treatment after the infection was present. The smallest scratch may mean death. Why play with such dangerous toys?

### Keeping Men on the Job.

We are equipped to do the very best surgery. This means that the men lose less time and have less disability when they return to work.

Our medical work consists of keeping the men on the job. We urge all employees to come to the medical department for consultation when they feel sick, such as a sore throat or when they feel a cold coming on, in order that by prompt treatment we may prevent more serious trouble. Our work does not interfere in the slightest degree with the outside doctors. Practically the only cases we treat in a medical line are those that would not go to their family physician for treatment. If the employee needs medical treatment at home we advise him to call his family doctor. If he cannot afford to pay for medical treatment, we make arrangements for him to get the very best care possible in one of the hospitals. We will always see that the employee or his family gets proper medical care. We want to make our employees feel as free as possible from the worries of family sickness.

### Examine Applicants for Work

We are now making physical examinations of all applicants for employment. We do this, not because we want to keep the man with a defect from getting a job, but rather that we should place the man with a defect on a job where he will

Corner of Laboratory in Medical Department of the Massey-Harris Co. at Toronto works.

not be injured by the work he has to do. We also make these examinations in order to keep out of the plant contagious disease. We make the examination in such a manner that no man can object to it. He steps into his cubicle in the doctor's office, strips to the waist and removes his shoes and stockings and is then inspected and examined from head to foot. He is told of any defect that he may have and advised how to take care of it. During the examination he is also instructed regarding "safety first." Applicants are categorized in one of five categories, according to their physical fitness. Employees with curable defects are instructed as to ways and means of having their condition cured, and close tab is kept on them until they get fixed up.

The sanitation, ventilation and lighting of the factories and offices are constantly under inspection and are gradually being improved.

### Bettering the System

We are constantly on the look out for ways and means of increasing the safety of the employee. When an accident occurs, a form is sent at once to the foreman for his report. He must describe how the accident happened, how long the man has been working on the job, and who instructed him in his work, and is also asked who is to blame for the accident. He is also requested to make suggestions as to how such accidents may be prevented in the future. This brings to the foreman his responsibility for all accidents in his department. We feel that if a foreman is imbued with the idea of safety that he will make his shop safe. From one of our shops there came many eye injuries, and it was soon noticed that the foreman was frequently appearing with a foreign body in his eye. We insisted that he wear goggles and, as a result, the eye injuries in this shop have been reduced at least 90 per cent.

DR. HERBERT BAKER, B.A., M.B., F.A.C.S.,

Director of Massey-Harris Medical Department. Photo taken in the Consulting Room at the Toronto works.

### A Busy Day's Work

Our service nurse at Toronto works is on the road in her car from 8.00 a.m. till 5.00 p.m. She makes from 12 to 15 calls a day. Foremen are instructed that all employees off work three days must be reported to the medical department with the reason of absence given, if possible. Cases of sickness are called on by the nurse and letters of appreciation of this work are constantly being received. We feel that this is one of the best parts of our work.

We keep accurate record of all patients that come into the department and of everything we do for the employee. At the end of the month this is chalked up against the department from which the patient comes and, in this way, we can keep tab on the accidents and sickness by departments.

It is the policy of this company to make a man satisfied with his job, and it is for that reason this department has been formed. We are trying to make the conditions under which our men work as sanitary and pleasant as can be. We want our employees to come to work free from worry and it is the duty of this department to remove these worries as much as possible.

Health is the workman's greatest asset. He cannot work without it and he can do the best work when he is in the best condition. We are here to advise him how to keep fit and we are trying to keep our plant free from conditions that would injure his health. We want every employee to know this and to feel perfectly free to come to us at any time for this advice for himself and his family.

NURSE HILL

Starting out on one of her daily visits to the homes of sick employees. This is a service that is greatly appreciated, and forms a strong tie between the homes and the company.

Appended are some figures from the March report that will give an idea of the amount of work done by the medical department:

**MASSEY-HARRIS COMPANY, LIMITED.**

**Report of Medical Department for the Month of March, 1921.**

| | Toronto. | Weston. | Brant'd. | Verity. | Bain. |

# Season Cracking of Brass And Other Copper Alloys

IN SPEAKING before the institute of metals, H. Moore, O.B.E., B. Sc., S. Beckinsdale, B. Sc., and Clarice F. Mallison, M.B.E., B. Sc., have the following to say regarding the season cracking of brass and copper alloys.

Numerous specimens of brass in which season-cracking has occurred have been examined and an investigation made of the causes of season-cracking, the detection of liability to fail in this way, the mechanism of the process by which the cracks form and develop, the effects of variation in composition, structure and physical properties such as hardness, and the prevention of season-cracking. Among the more important conclusions are the following:—

Season-cracking occurs in a great variety of industrial brasses, differing widely in composition, degree of purity, microstructure, and physical properties, but occurs only in material which is maintained in a stress, either by external constraint or more commonly by internal stress. Corrosion of the surface and sometimes of the walls of the cracks is frequently associated with season-cracking, but corrosion effects are not always visible. Season-cracking may occur in brass coated with continuous protective layers such as lacquer, though nickel-plating is probably completely effective in preventing season-cracking, if a sufficient and continuous coat of nickel is secured.

Highly stressed articles, capable of developing season-cracking in certain conditions, may be kept for years in reasonably pure atmospheres without showing any sign of cracking, and there appears to be no reason to anticipate the development of cracks so long as the condition of the surrounding atmosphere does not change. Some agency additional to the presence of initial stress appears to be necessary for the development of season-cracks. Surface defects do not appear to contribute to the development of season-cracks in brass to any important extent, and corrosion does not necessarily favor their development. Mercury, ammonia and ammonium salts readily produce cracks in brass which is sufficiently stressed in tension. It is probable that traces of ammonia in the atmosphere are an important agency in inducing season-cracking of stressed brass.

Season-cracks almost invariably follow an inter-crystalline path and the cracks produced in stressed brass by mercury or by ammonia are of the same intercrystalline type. Ammonia appears to have a specific and selective action upon the intercrystalline material of brass, weakening it sufficiently to cause cracking if in tension. Mercury has a similar intercrystalline weakening action.

The greater the degree of hardening by cold work the less is the brass affected by the intercrystalline weakening action of ammonia or mercury, although it is probable that weakening may occur whatever the degree of hardness of the brass.

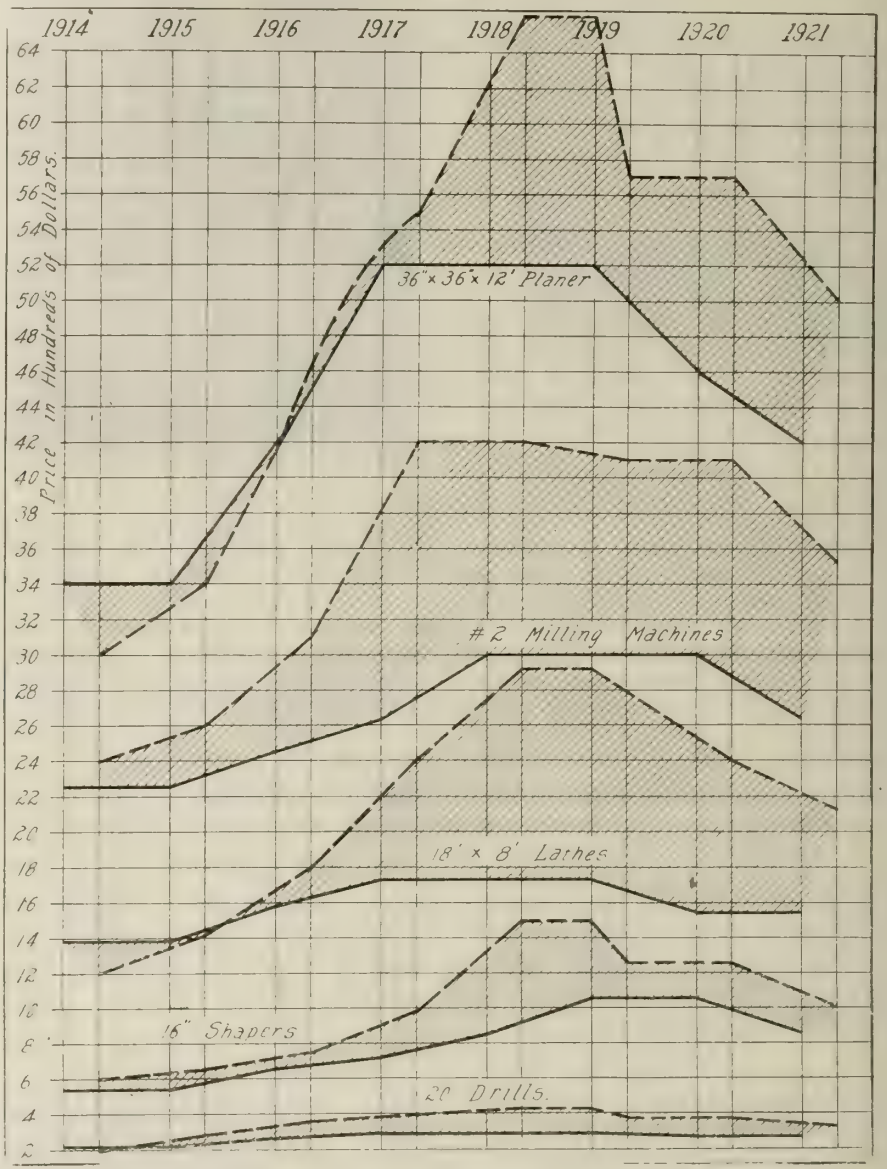
It is probable that the behaviour of a copper alloy submitted to the combined effect of tension and of ammonia or mercury is a reliable index of its liability to fail by season-cracking. This liability appears to diminish as the zinc content of the brass is reduced. Copper and zinc-copper alloys containing less than about 10 per cent. of zinc are unlikely to fail by the development of season-cracks in service.

A suitably controlled low-temperature annealing which will remove stress sufficiently to ensure freedom from season-cracking with little or no effect on the hardness appears to be the most effective safeguard against failure by season-cracking and might well be applied to all brass articles made by cold-work operations capable of inducing permanent internal stress.

The undoubtedly intercrystalline character of season-cracks in brass appears to be fully explained by the selective weakening action of a chemical substance on the intercrystalline material. The authors are unable to find in the results of their work any evidence indicating that season-cracking is the result of viscous flow of the intercrystalline cement.

# Rise and Fall in the Price of Machine Tools

## The Peak in Prices Came About August of the Year 1918—Many Machines Are Worth More Than Formerly Owing to Improved Design Following the Experiences of the War



BY J. H. RODGERS

SOME appreciation of the effects of the war and the subsequent conditions arising therefrom may be gathered from the accompanying chart, which illustrates the rise and fall in the prices of a few of the principal types of machine tools over a period of seven years. The graph was developed from the records of two leading dealers in this class of equipment.

The full line represents the actual price (f.o.b. Montreal) on the particular size and type of tool designated by one dealer, while the broken line shows the rise and fall of corresponding tools on the percentage basis, the price in 1914 being taken as 100; the latter being based on the records of the second dealer. It will be seen that there is considerable range in the price of similar tools by these two individual dealers, and it may be gathered that a fair average price for said tools would lie somewhere within the shaded portion of any section.

In explanation it might be stated that the full line which has been developed from prices given for a particular make of machine of a specified size or type, will represent, very accurately, the fluctuations on that tool, while the broken line is a graphical illustration of the price movement of the different machine tools in general. It will be noted that in nearly every case the peak of prices existed in 1918, and it was about August and September of that year that the highest figures were recorded.

The present tendency is towards lower quotations on nearly all lines of standard equipment, but many factors combine in preventing a too rapid decline to what many might consider normal prices. Probably the one outstanding feature in this connection is the prevailing high cost of production, a condition that not only restricts the manufacture of machine tools, but detracts from the activity in many lines of industry that would, under normal conditions, be large consumers of metal working machinery. In this respect, however, it must not be overlooked, that no little percentage of increased cost of standard equipment might well be marked down to the improvements that have been made in design as direct result of the experience and knowledge gained by tool designers during the years of the war.

THIS CHART SHOWS YEAR BY YEAR THE CHANGE IN PRICES.

**Price Range in Per Cent. on Machine Tools from 1914 to 1921**

| | 1914 | 1915 | 1916 | 1917 | 1918 | 1919 | 1920 | 1921 |

# The Trend Toward Automatic Production

## Development of Machine Tools—Does Such a Thing as a Completely Automatic Machine Exist?—Operators Have Been Relieved of a Large Part of Their Physical Burden

*By A. L. De LEEUW, Consulting Mechanical Engineer

IT is but slight exaggeration to say that, next to the pre-war cost of living, no phase of the past is regretted so much as the gradual disappearance of the "all-around mechanic." Those who are optimistically inclined by nature merely say that they are mighty hard to get nowadays, and the pessimists believe that the species will be extinct in a few years and that the new generation will view the skeletons of the dodo and the all-around mechanic exhibited side by side in the same glass case. Hearing some of the talk and reading some of the articles written about the "decline and fall" of the all-around mechanic, one would come to the conclusion that the present high development of our mechanical equipment and processes is entirely due to his efforts, and that all we have accomplished along these lines will disappear with him. And yet it is highly probable that the same man who so earnestly bewails the scarcity of all-around mechanics would be embarrassed to know what to do with a dozen if they should apply for a job.

The fact of the case is there are so few of them wanted, and so few are wanted because only a few are needed. This does not mean that there may be a temporary shortage here and there at some time or other, but that, if we could restore the conditions of thirty years ago, we would have a lot of men who would not fit in with our present-day methods and, on the other hand, there would be a great dearth of machine operators and specialists who could turn out a fair day's output. Our manufacturing systems, methods and machinery have changed, are still changing, and like everything that isn't hopelessly dead, will continue to change forever and ever.

### Hand Versus Automatic Action

The entire development of the machine tool has been in the direction of replacing skill of hand by the automatic action of a machine, and the worker has changed with it. It is true that the mechanic made the machine tool, but, in its turn, the machine tool made the mechanic. To a certain extent, the old-time mechanic is still required for the building and development of new equipment, new tools and new methods; but he has lost his importance as a factor in production. It is sometimes claimed that our present-day mechanic is not so good a man as his predecessor of thirty years ago; but, personally, I am of opinion that the reverse is true. The man of to-day is confronted with more complicated problems than were met thirty years ago, and he solves them.

When machine tools were few and of simple construction, arranged to work at slow speed and with fine feeds, and when shop methods did not call for that high degree of accuracy which is required for interchangeable manufacture, it was not a difficult matter for a man to learn to operate all the machine tools of that time. At the present, there are so many more machines, and they are so much more complicated, and require so much more knowledge, that it is not fair to expect that any one man should know about them, and much less should be able to handle them all.

Our manufacturing systems, methods and machinery have changed, are still changing, and, like everything that isn't hopelessly dead, will continue to change for ever and ever.

It is sometimes claimed that our present-day mechanic is not so good a man as his predecessor of thirty years ago; but, personally, I am of the opinion that the reverse is true. The man of to-day is confronted with more complicated problems than were met thirty years ago, and he solves them.

It was said that the development of the machine tool consisted in adding automatic features. At one time a lathe was called an automatic lathe because it had automatic feed. Even now, we can find people who speak of an automatic milling machine, meaning merely a milling machine with automatic feed in more than one direction. Gradually more and more automatic features were added, but even to-day one cannot say that a completely automatic machine exists. In fact, such a thing would not be humanly possible. The machine must always receive some attention from an operator. Tools must be watched, adjusted or replaced; material must be renewed, and the machine itself must be watched and, if necessary, adjusted or repaired. We do not expect to be able to avoid the necessity of doing these things. We cannot hope to build a machine which will repair itself or go to the warehouse and fetch new stock for itself. On the other hand, we have done things in the last thirty years which seemed, at the beginning of that period, very far removed from realization.

Many automatic machines did exist thirty years ago, but not in the standard lines of machine tools. A Jacquard loom is a highly developed automatic machine, and so is a self-binder. Many more instances could be given of automatic machines which existed then. There were also in existence many highly developed and very ingenious automatic machine tools, but they were mostly special machines, developed by some concern which made pieces in sufficiently large quantities to make a specially developed machine economical. Outside of such cases, however, there were only two automatic machines: the screw machine and the gear cutter. In addition, practically all machine tools had some automatic feature, such as feeds.

### List Is Growing

Since that time, we have added to our list of automatic machine tools as well as to the list of automatic features contained in such machines. We now have automatic screw machines for bar work, chucking machines, chasing machines, gear cutters, hobbers, milling machines, screw slotters, nut tappers, etc. In addition, there are a number of automatic machines used for more or less special purposes, like the Mult-Au-Matic; and many machines developed by large concerns for the requirements of their business. Among these latter machines may be found instances of the highest development which the automatic machine has reached at the present time.

The automatic screw machine, as existing thirty years ago, was a single spindle machine built along the lines of the old-time turret lathe, with the same kind of turret, the same kind of cross-slides; in fact, differing from the existing turret lathe only by the fact that cam-drums were used to give the various motions to the turret and the cross-slides, and that the spindle was provided with an automatic device for advancing the stock and chucking it at the proper time. Nowadays we still have this general type of automatic screw machine, but every single part has been modified so as to make it more adaptable to an automatic machine. It has developed into our present-day machine by dif-

*From "Industrial Management."

ferentiation and specialization. Mechanical movements have been developed which make quick chucking, quick return and quick turret indexing possible. But, in addition, other screw machines have been developed of which the main features differ radically from the old type. Some have been developed for the particular purpose of making small pieces and rapidly, others for making larger pieces, much larger than was ever contemplated when the first automatic screw machines were built, and still others have been developed for large production by the introduction of the principle of the multiple spindle construction. This latter development is almost equivalent to the development of a new type, for methods had to be devised and difficulties had to be overcome which were entirely foreign to the original machine. Some machines have been designed for large production where rapidity of production is the prime requirement, but where the machine requires considerable time for resetting, other machines have been developed for smaller quantities and the setting time has been reduced to a minimum, perhaps at the expense of rapid production of the individual piece. It would seem that in the immediate future we may expect further development along these lines. It would seem probable that the single spindle screw machine will be further developed along the lines of ease in setting up, while the multiple spindle screw machine, which of necessity can only be used profitably for large production, will be still further developed as to rapidity of operation, even if the time and setting would have to be increased.

### Importance of Secondary Operation

An entirely different line of development of the screw machine is found in the attachments which have been gradually added. In a great many cases, a piece is not entirely finished when it comes off the screw machine. If it takes 20 seconds to make a piece on the screw machine, and then it takes 20 seconds for a secondary operation, there is very little advantage in reducing the original time by 1 or 2 seconds. But if it is possible to do the secondary operation on the same machine while the first operation is going on, a gain of 50 per cent. is made in the total machine time; and not only that, but all the labor of re-handling, re-inspecting, storing, and the difficulty of control, are all overcome at one time. Take, for example, a screw of which the head must be slotted. Let us imagine that it requires 20 seconds to make this screw, and that an operator handles five machines at one time. Then the cost per piece is the same as if the operator spent four seconds per piece, and four seconds will be the measure of the labor cost. After the piece is made, it must be sorted out from the chips and inspected before it can be given to the next operator for slotting the head. If this slotting can be done also in four seconds, the cost of secondary operations will easily be twice as much as the cost of making the screw. A slotting attachment on the screw machine will do the slotting while the other operations are under way, so that the entire labor cost of the piece will be four seconds. In addition, the slotting attachment deposits the screw in a little receptacle away from the chips, so that it is possible for the operator at any time to gauge his work, and if he finds that some readjustment is necessary, he will not have to throw away more than a fraction of the screws contained in this small receptacle. It may be expected that in the near future attachments or arrangements of machines will be made so that the piece will be entirely complete (up to the point of hardening, if hardening is required) when it drops off the screw machine.

> Watch the secondary operation. If you can possibly do this operation on the same machine while the first operation is going on, a gain of 50 per cent. in the total machine time is made. Not only that, but all the labor of re-handling, re-inspecting, storing, and the difficulty of control are overcome at the one time.

### Two Distinct Lines

Automatic chucking machines have, so far, developed along two distinct lines: the one is the development of the hand chucking machine, and does practically nothing except operations which can be done on a lathe; the other is a machine which might be considered as a peculiar development of the drill press; it does such operations as hollow milling, drilling, reaming, facing (such as would ordinarily be done on a drill press), threading and tapping. These machines are made either one or two end. Whereas the other type of chucking machine is mostly for round work, this type takes care of work of any shape which can be reached by the tool spindles. This class of machine is essentially a multiple spindle machine. The first type is best illustrated by the Potter and Johnson machine or the Mult-Au-Matic though the screw machine has also been used as a basis for this type. The most important recent development in this class of machines is along the lines of magazines or hopper feeds. Incidentally, these two terms are often confused. A magazine is a device in which the pieces are deposited in a certain way and which then delivers them to the spindle at the proper time and in the proper manner. A hopper feed does not require the pieces to be laid in any particular manner, but takes them from a hopper and places them automatically in the proper position to be delivered to the spindle. A great variety of magazine and hopper feeds have been developed, and many other arrangements may be expected in the near future, for the tendency nowadays is to do away to the fullest possible extent with all hand operations. Whereas the Potter and Johnson machines, or any of the screw machines arranged for chucking, are single spindle machines, the Mult-Au-Mac is a multiple spindle machine. The same two lines of development which may be expected in the screw machines may also be expected in the chucking machines.

An entirely different line of automatics is found in the automatic finishing machines. Such machines are arranged for secondary operations only. The existing types are best illustrated by the automatic chasing lathe and the Fay lathe, not because they are more representative of their types, but because they are more generally known. As a matter of fact, there are numerous machines of this type in existence, some for turning, some for grinding, some for threading or tapping only, and some for various combinations of these operations. This type of machine is still in its infancy, so far as standard machines are concerned; it has been very highly developed by individual concerns for their special work. Here, also, we may expect a future development of magazine or hopper feeds.

### If Work Is of Short Duration

Wherever the machine operation is of relatively short duration, we may expect such development of the magazine or hopper feed, because a large percentage of the total time can be saved in this manner; but where the machine time is very large as compared to the time required for placing a piece in the machine, magazine or hopper feed cannot accomplish much saving of time and will probably never be employed. Machines of this type are the gear cutter and hobbers. In a great majority of cases, the work done by a gear cutter or hobber requires a great deal of time per piece; but there are cases where the gear to be cut is so small that the time for chucking is a large percentage of the total time. In such cases we may expect magazine feeds; and, as a matter of fact, such magazine feeds are employed where very small gear or pinions have to be cut, such as for watch works.

One of the best examples to show how the world is striving for automatic machines is found in the automatic nut tapper. Here it would seem exists a difficulty which cannot be overcome. After a number of nuts are tapped, the tap will be full and must be taken out of the machine and the nuts shaken off. At a first glance it would appear that this is a condition which cannot be altered.

The tap may be made as long as possible, but finally it will be full and must be taken out. And yet the mechanic's ingenuity has overcome this seemingly insurmountable difficulty by the simple expedient of using the bent tap.

Power presses are sometimes considered as not belonging to machine tools. Whether this view is right or not, it cannot be denied that they are doing their duty in metal manufacturing shops. They, too, have responded to the necessity of obtaining the greatest possible production with the least amount of manual labor. Many devices have been developed for the purpose of making the press more or less automatic. Dial feeds, roll feeds, magazine feeds are quite common and the so-called eyelet machine is as good an example of an automatic machine as any in existence. In line with this class may be mentioned wire forming machines, nail and wood-screw making machinery, and the like.

There is left one class of machine tools which has not been developed to any extent in the direction of automatic functioning, though there seems to be no essential reason why this should be so. The milling machine, though highly developed as a machine tool, has not been made automatic in the sense that the lathe has been transformed into the automatic screw machine. However, there are two classes of milling machines which have, to a certain extent, automatic features. These are the semi-automatic milling machines and the continuous milling machines. Though provided with features which obviate, to a certain degree, manual operation, they lack those features which we instinctively connect with the idea of an automatic machine tool, and that is the presentation of various tools to the work and the automatic presentation of new work to the tool. Such features may be found in a number of special automatic machines built by various concerns for their own needs, but are not embodied in any of the standard milling machines on the market.

### Quantity the Big Feature

The one outstanding point which limits the usefulness of the automatic machine is quantity. The time required for setting up an automatic machine for a new piece of work must necessarily be relatively large and, furthermore, it is almost unavoidable that some pieces of work should be spoiled during the process of setting up. This lost time of setting up together with the lost work must be weighed against the advantages of the automatic machine. As a rule, too much emphasis is put on this unavoidable loss of time, and a great many operations which are now done on manually operated machines might be done on automatics, if a careful analysis were made of all conditions. This matter was forcibly brought to the writer's attention by the following incident:

## A HINT TO THE MANAGER

Not only has the automatic machine arrived, but it is still arriving in greater and greater numbers. Luckily many managers have wakened up to the fact that the trend of the times requires automatic machinery wherever it can be employed.

Instead of installing an automatic machine when the conditions are such that no one could possibly doubt its economic advantage, the live manager of to-day should reverse the process and take for granted that he must employ an automatic machine unless he can clearly show that it will not pay.

A certain part, intended for a clutch, about six inches in diameter and about eight inches long, was made in quantities of fifteen at a time, and only one lot of fifteen per year. Without analyzing the thing at all, it was taken for granted that the quantity was entirely too small for an automatic machine and even for such type of machine as the Gisholt, so that it was customary to make these parts on the engine lathe. The writer had this job transferred to a Gisholt machine in an experimental way, and it was found that the first piece was finished on this machine (including the time required for setting up) before one piece could be made on the engine lathe. The next lot was transferred to a Cleveland automatic, again in an experimental way, and it was found that the first piece was made on the Cleveland (again including the time required for setting up), before a single piece could be made on the Gisholt. Of course, this would not happen every time, but the incident showed how necessary it is to analyze the job carefully before concluding that it is not fit for an automatic.

Against the losses incident to the automatic machine, we must figure the advantages of it. In a broad way, these advantages are the following:

A relatively unskilled man can do the work, and this man can run a number of machines; a single highly skilled man being required for the setting up and inspecting of a number of groups of such machines.

The machines run continuously, without requiring rest periods, and without reduced energy at various times of the day.

Production is assured at a known rate, so that it is possible to plan with greater assurance than when depending on the results of manual labor.

It is quite natural that the manager should hesitate to instal automatic machinery unless the balance is very strongly in its favor. On the other hand, it is a fact that when the automatics are once installed, many jobs are found to which they are adapted, after the machines have been working for some time. It would seem that there is another type of machine needed to fill the gap between the highest developments of automatic machines and the purely hand-controlled machines. To a certain extent, some existing machines fill these requirements. The Gisholt machine, the Jones and Lamson, and a great number of hand screw machines have some of the essentials of this intermediary class; but they still require too much skill and manipulation on the part of the operator to class them among, or even close to, the automatics. A type of machine might be developed which does every single operation automatically, but on which every operation must be started by hand, thus avoiding a large portion of the complicated mechanism of the purely automatic machine, and at the same time largely reducing the time for set-up. Machines of this class might be called "programme machines," because they would have to be set up for a number of single operations and the operator would get a programme of the sequence of operations which he must follow.

### Special Automatics

Frequent mention has been made of highly developed automatic machines designed and built by concerns which are manufacturing on a large scale. In such machines, many operations may be combined which can never be combined in the standard machine. Drilling, boring, reaming, tapping, milling, slotting, key-waying, turning, all may be done on one machine. Such machines, as a rule, are of the multiple spindle type, and require the highest degree of workmanship in their construction in order to be successful. They are costly to make, and, as only one—or at the best only a few—are ever built, it is very seldom that there are not a number of "kinks" left. Consequently, such machines require a relatively large amount of repair. The fact that a large number of tools are used in one machine means stopping it every time one of the tools breaks down. Many other disadvantages could be brought up against this type of machine, and are being brought up, particularly by people who are not familiar with their operation. However, notwithstanding all the drawbacks mentioned many machines of this type have been

built, are operating successfully, and are wonderful factors in economy. It is a human tendency to make much of difficulties before they are met. The objection was raised against the early railroad that there might be a cow on the track. We all know what Stephenson said about it. It is true that since the introduction of railroads there have been many cows on the track, but we have not discarded railroads.

All the difficulties and disadvantages mentioned above exist and should be carefully weighed, and when that is done, we can express it in a simple way and say that we estimate the efficiency of the machine to be 90, or 80, or even 50 per cent. This simply means that, if we should not meet any trouble, and the machine should be capable of turning out 8,000 pieces per week, then, under the conditions as we estimate them, our output will be only 90 or 80 or 50 per cent. of 8,000 pieces. And that must be the number of pieces upon which we should base our calculations. Whether provision should be made for the amortization of the investment in two years, or five, or ten, depends very largely on the nature of the machine as well as on the stability of the product. If the machine is of such a nature that it can easily be changed over for the production of some other piece made in that factory, or if the piece has been made for many years and there is no prospect of its being discarded for many more years to come the time for amortization may be estimated as quite long. But if the machine would have to be discarded when the piece is made obsolete or when the probable life of the piece is only a few years, or both, then we must figure on a short useful life of the machine and on saving sufficient in production to pay for that machine in the estimated time. It is always a dangerous thing to build such specialized machinery for a new product, not only because the product may have a short life, but because, even if it may have a long life, it is highly probable that it will be changed in some details before it is completely standardized.

### Do Automatics Lower Standard of Workmen?

Contrary to the belief that automatic machinery tends to lower the standard of the workman, it is the writer's conviction that the general tendency is to elevate that standard. Not only that, but automatic machinery creates a training school in the shop where it is employed. The man who delivers the stock and cleans out the machine by and by becomes the man who makes minor adjustments and learns to measure accurately. If he has the necessary mental capacity it is but a short time before he is a full-fledged operator, and again, if he has a higher mental capacity, he will readily develop into a tool-setter or a foreman.

In conclusion it may be said not only that the automatic machine has arrived, but that it is still arriving in greater and greater numbers, and that only recently many managers have waked up to the fact that the trend of the times requires automatic machinery wherever it can be employed. Instead of installing an automatic machine when the conditions are such that no one could possibly doubt its economic advantage, the live manager of to-day should reverse the process and take for granted that he must employ an automatic machine unless he can clearly show that it will not pay.

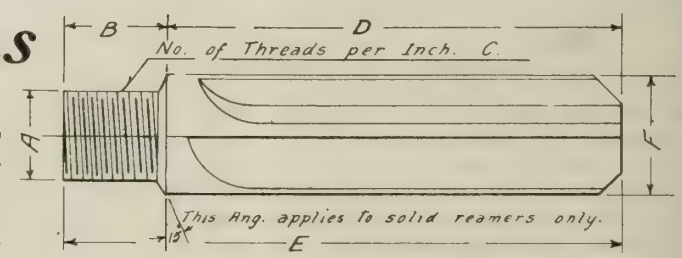
## WHAT IS RADIUM?

The question is often asked, What is radium? To put it briefly, radium is a metal that is described as having a white metallic lustre. It has been isolated only once or twice, and few persons have seen it. It is ordinarily obtained from its ores in the form of sulphate, chloride or bromide, according to the United States geological survey, department of the interior, and it is in the form of these salts that it is usually sold and used. These are all white or nearly white substances, whose appearance is no more remarkable than that of common salt or baking powder. Tubes containing radium salts glow mostly because they include impurities which the radiations from the radium cause to give light. Radium minerals are very rarely, if ever, luminescent.

## SPEED IN RIVET CUTTING

What is believed to be the record to date for cutting rivets in the dismembering of steel freight cars was recently established by an operator who cut out 1,038 rivets in two hours and 46 minutes. Of this number 683 were ⅝-inch rivets, 228 were ¾-inch rivets and 127 were ⅞-inch rivets.

The cutting was done on a standard Erie car under general yard conditions, the operator taking the rivets as they came, working inside, outside and under the car. The car was one that had been retired from active service and that was in the car shop for repair, the rivets and plates being covered with heavy scale and rust, thereby rendering the cutting extremely difficult.



It is said that the record applies not only to the number of rivets cut in the time required, but also to the low consumption of gases used, the job taking only 384 cubic feet of oxygen and 83 cubic feet of acetylene.

# *Reamer Proportions*

Having a considerable number of holes to ream, here is how one manufacturing plant got over the difficulty. They made solid reamers of the design shown, giving certain proportions to the different sections of the reamer.

These have proved of great productive quality, and the venture has saved them considerable cash since its first being adopted.

*By J. H. Moore*

SOLID SCREW SHANK REAMERS

Sizes not less than $\frac{7}{8}$" and not over $1\frac{3}{8}$"

# Improve Your Powers of Perception—Try This Contest

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

The winner of the May 5th contest, Sam Fishman, 16 Farm St., Point St. Charles, tells us that up to this, his first attempt, he has been too busy to try the contest much as he wanted to. As he happened to be the only contestant with a correct list, it's perhaps just as well for the others that Sam has been so busy.

### CONTEST FOR MAY 26TH ISSUE

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1 What to do if you require unusual precision.

2—A piece of good advice.

3 A case where it paid a certain firm to change their existing methods.

4—Something that is not a pugilist—yet can hit hard.

5—A case where a postcard, if used correctly, brings important news.

6—Something that should interest the small shop owner.

7—How to eliminate costly repair bills.

8—A case where a product can be furnished to suit any country.

9 How to secure civic co-operation.

10 Something you can withdraw without injuring the work.

11 A product said to allow a much wider scope of work, without loss of efficiency.

12 How to secure a practical time saver.

### These are Correct Answers for List from May 5th Issue:

1—International Business Machines Co.

2—Morse Chain Co.

3—Canadian Hart Products, Ltd.

4—Geo. D. Roper.

5—Geometric Tool Co.

6—Wallace Barnes Co.

7—Landis Machine Co.

8—Armstrong-Whitworth of Canada, Ltd.

9—Acme Machine Tool Co.

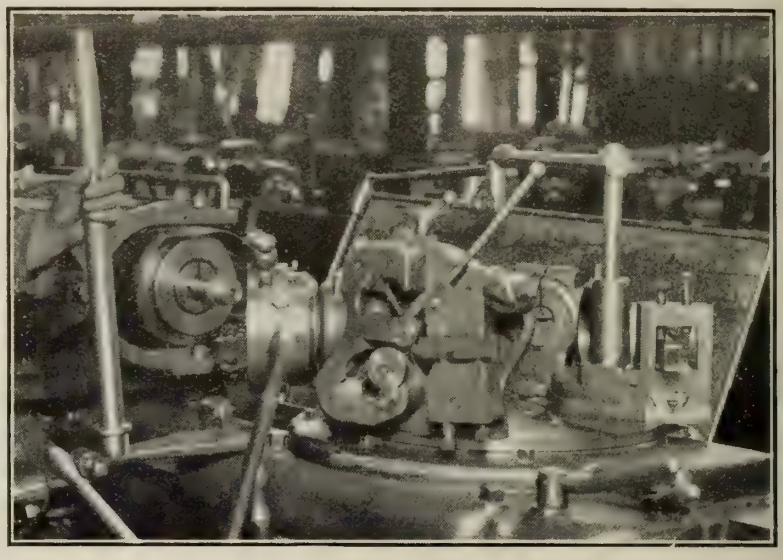
10—United Alloy Steel Co.

11—Greenfield Tap & Die Corporation.

12—Bellevue Industrial Furnace Co.

## Closing Date for This Contest is June 16th

# Producing a Pump Rod on the Turret Lathe



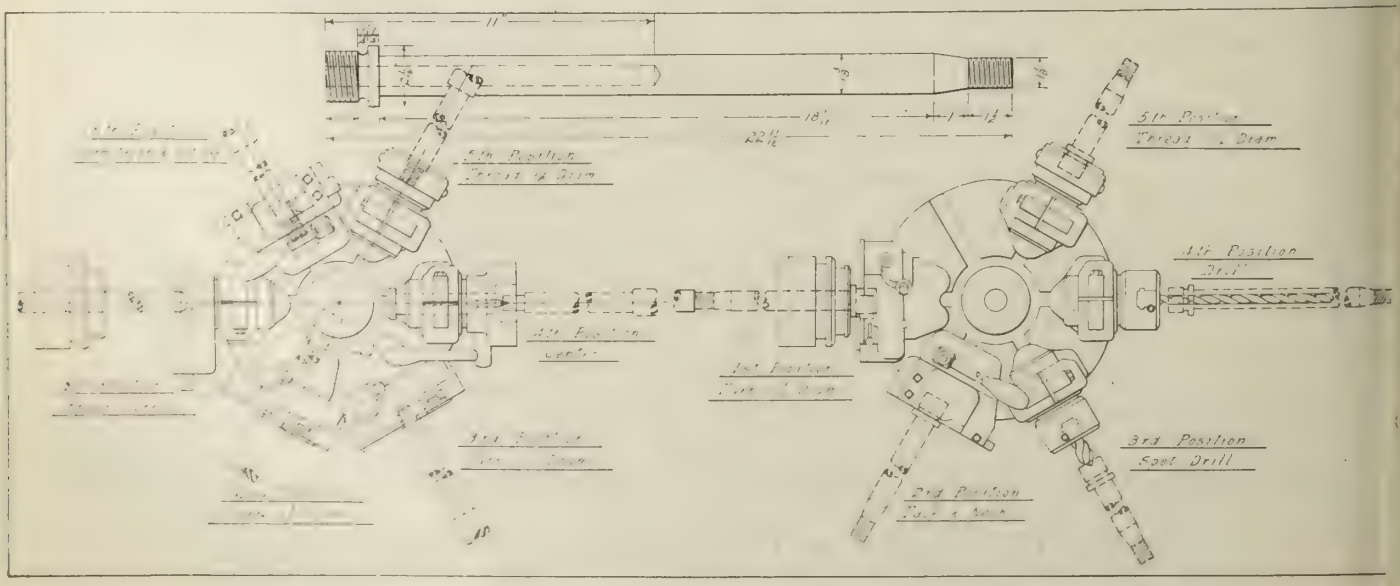
## Rod Completed in Two Settings—Material, Cold-rolled Steel Bar Stock—Standard Equipment Used—A Rod is Finished in Eleven Minutes, This Including Both Operations

ON page 76 of the April 7 issue of Canadian Machinery we published an article on the production of a pump rod. At that time we suggested that readers, or makers of machines, let us have their views on the problem, and here is how the Jones & Lamson Co., Springfield, Vt., would proceed to mahcine the part.

The piece is understood to be made from cold rolled steel bar stock, and we would finish it in two settings, using our regular standard equipment on a 3 x 36-inch Hartness flat turret lathe equipped for bar work. This machine handles bar stock 3 inches in width up to 36 inches in length.

In the first operation the piece is held in our automatic collet chuck. The automatic chuck and roller feed handle rough bars of round, square, octagon, hexagon and flat stock, presenting a new length and gripping it while the machine is running. This chuck is one of the essential features of the Hartness flat turret lathe in its equipment for turning work from full lengths of bars, as its strong and unyielding grip gives a rigid presentation of the work which is of paramount importance. The jaws are of unbreakable form and may be readily made for any size or shape of material within the spindle's capacity.

At the first position, break down the corners of the stock with a chamfering tool fitted with a bell-mouthed bushing, the taper of the bushing being the same as the taper on the chamfer of the work. This is preparatory to turning in the second position. Here the 1⅜-inch diameter is turned, using the roller back rest turner, the roller supports of the turner following the point of the cutting tool. The rolls on the roller turner run on straight headless pins hardened and ground. These pins are held by a rocker insuring an axis in parallelism with work. All adjustments are conveniently made and are the most direct and unyielding in resistance of working strains.



GENERAL VIEW OF THE TOOLS USED.

In the third position, the 1⅛-inch diameter is turned with a roller back rest turner, the roller back rest in this case being ahead of the point of the cutting tool, and resting on the finished 1⅜-inch diameter. By this method the 1⅛-inch diameter is brought concentric with the 1⅜-inch diameter.

In the fourth position the end is centered, using our roller back rest centering tool. Note that this is a lever operated fixture. It is customary to advance the carriage to a stop, lock it, and then by means of a lever-operated device the piece is centered by hand. We have found from experience that it is much better practice to center, using this fixture, than to center by using the star wheel, for advancing the carriage. Since the lever-operated centering tool is a very sensitive fixture to operate, it reduces the breaking centers to a minimum.

In the fifth position the 1⅛-inch diameter is fitted with a No. 4 Hartness automatic self-opening die. The automatic fixtures and the combination of the elements that determine the form

DETAIL OF THE ROD TOGETHER WITH TOOL LAYOUT FOR BOTH OPERATIONS.

ead, diameter and general dependabil-ty of the screws produced by this die re well known.

In the sixth position the taper is ormed and the piece cut off, using our ever-operated cut-off slide. The sliding ool block is closely fitted and gibbed to he base, which is bolted securely to the urret; a long lever and a small pinion urnish means for feeding the cut-off tool nto the work. While forming the taper he work is supported by means of a ushing placed at the rear of the cut-off lide bored to fit the 1⅜-inch diameter f the work. The production on this peration is 11 pieces per hour.

### Second Operation

In the second operation the piece is eversed and gripped in the automatic ollet chuck on the 1⅜-inch diameter inished in the first operation.

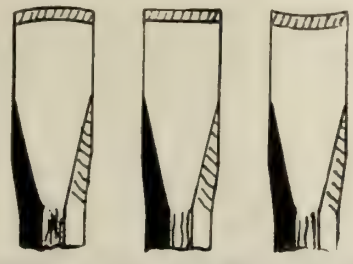
The work is located endwise by a stop n the spindle insuring a uniform dimen-sion in shoulder lengths.

In the first position the 1 11/16-inch liameter is turned, using the roller back rest turner. In the second position face and neck preparatory to threading, us-ing the lever-operated cut-off slide; in the third position spot preparatory to drilling. Any straight shank drill may be used and is held in a little giant drill chuck.

In the fourth position the long hole is drilled, the drill being held in a sim-ilar chuck; in the fifth position the 1 11/16-inch diameter is threaded by a No. 6 Hartness automatic self-opening die. The production on this operation is 12 pieces per hour, and the time for one piece finished complete in two opera-tions is 11 minutes.

## CHISEL ARTICLE

Do you know how to make a chisel? If so, do you know how to make a good chisel? These important questions are asked in a recent leaflet issued by the Joseph T. Ryerson & Son, Chicago, and here is what they have to say on the subject:



A very large percentage of the chisels now in use are not good chisels. They are not forged, shaped and hardened in the best way to give long life and ade-quate service. During the past few years we have secured valuable information from various chisel makers and users and pass it along believing that it will help you to turn out a tool far superior to those ordinarily furnished. Considering the making of a chisel from ¾-inch octa-gon tool steel, we suggest the following method:

### Forging

Cut off a length of steel, depending on the length of chisel desired, and heat up the end for 2 inches to a bright cherry red. Trim off two opposite sides so as to form a very blunt nosed tool. The object of this trimming is to do away with the danger of lapping when draw-ing out.

The horn of the anvil should be used in drawing out, inasmuch as this will have the least possible tendency to widen the piece, and therefore the minimum amount of "edging in" or hammering on the edge will be necessary. The reason a chisel should not be hammered on the edge is that the grain of the steel will thereby be distorted or, as you might say, "crumpled up," and this always has a tendency to weaken any metal. If in the final forging operation the chisel gets a little too wide, it can be very easily trimmed off on the emery wheel during the grinding operation. Draw the chisel out so that it will be about ⅛ inch thick at the end and about ⅜ inch thick about 1¼ inches back from the end.

The forging should be finished with light blows until the steel has almost lost color, but it absolutely must not be struck after the color has disappeared.

SKETCH 1, 2 AND 3, SHOWING THE DIFFER-ENT METHODS OF GRINDING CHISELS. NO. 3 IS BY FAR THE BEST FOR ORDINARY WORK.

It is a good thing to reheat the steel to a dull red without using any blast, and give it a second hammering with light blows until the color has again almost disappeared. The four important things to remember in forging a chisel are, therefore: Draw out at a good cherry red heat, finish with light blows at a dull red heat, do not hammer after the color has disappeared, hammer as little as possible on the edge and then only when the steel is fairly hot.

### Grinding

Grind the chisel before you harden it, as you can grind faster in this way with-out the danger of drawing the temper. The shape of the edge of the chisel is very important, although it is a thing which is often overlooked. Sketch No. 1 shows a chisel ground with a concave edge. If this chisel is driven on to a flat surface, it is obvious that a great strain will be put on the corners, and they are sure to break off. Sketch No. 2 shows a chisel ground with a perfectly flat edge. If this chisel is driven down onto a flat surface and held perfectly straight, the cutting strain will be distributed evenly over the entire edge, and the chisel should be satisfactory. It must be re-membered, however, that it is almost impossible to hold a chisel absolutely straight and, therefore, either one cor-ner or the other will be severely stressed by the chisel being tilted over. Sketch No. 3 shows a chisel ground with a slightly convex edge, which is by far the best for ordinary work. The corners of a chisel are always the danger point, and with the convex edge these corners are protected even when the chisel is tilted over considerably to one side or the other.

### Hardening and Tempering

After the chisel has been ground to the desired shape, heat it to a dull cherry red color for about 2½ inches from the end and quench it vertically in cold water to a depth of 1¼ inches, moving it up and down until no red color is left in any part of the steel. The part which has been drawn out should now be polished with emery cloth and the temper drawn to a dark purple or a blue by holding the chisel over the fire or in a furnace. Al-ways draw a chisel a little more in winter than in summer. We have suggested hardening the chisel back very much fur-ther than is usual. The reason is that a chisel so made can be ground a great many times without redressing. Inas-much as grinding is cheap and redress-ing is expensive, considerable loss can thereby be avoided.

## SOLDERING SHEET ZINC

Soldering sheet zinc is an easy task, if you are familiar with the work. How-ever, if you have never handled such material, read these few hints.

Most failures in the attempt to secure joints of the desired strength and qual-ity, where sheet zinc is concerned, are due to overheating the metal. Too long an application of the soldering iron is often responsible for unsatisfactory re-sults. Only a quick pass of the solder-ing iron over the metal is needed to pro-duce a sound joint. If the contact is prolonged the zinc may melt or its in-ternal structure become so changed by over-heating as to produce a weakening of the metal. Sheet zinc melts at a tem-perature of 786 degrees F. It is usual to heat the soldering iron until it be-comes a dull red, and that is sufficient to perform the soldering of joints of sheet zinc. Solder of half-and-half grade is suitable; but preceding the actual operation, a "cut acid" fluxing solution, or a solution of zinc chloride acidulated with muriatic acid, should be applied to the metal being prepared for the work. Care must be exercised to ensure the sheet zinc being first free from dirt or grease, particularly along the line to be soldered, and the seam sur-faces must be in perfect contact.

# WHAT OUR READERS THINK AND DO

## SCREW CUTTING QUERY

By JOHN S. WATTS.

REFERRING to the article under the above title, on page 74 of Canadian Machinery May 5th issue, I would solve the problem of finding the change gears to cut this thread as follows: The lead screw having four threads per inch, would have to travel $4 \times 9\frac{7}{8} = 39.5$ revolutions to travel the carriage $9\frac{7}{8}$ in., and the change gears must cause the lead screw to turn 39.5 revolutions while the spindle revolves six times. The ratio of speeds is therefore 39.5/6, and converting into whole numbers by multiplying by two, we get 79/12, that if a 79 tooth gear on the spindle, and a 12 tooth pinion on the lead screw, would give the exact ratio desired.

As we have neither of these gears available, we will try a double reduction, and splitting the ratio 39.5/6 into factors, we get

$$\frac{39.5}{6} = \frac{5 \times 7.9}{2 \times 3} = \frac{(5 \times 10) \times (7.9 \times 10)}{(2 \times 10) \times (3 \times 10)} = \frac{50 \times 79}{20 \times 30}$$

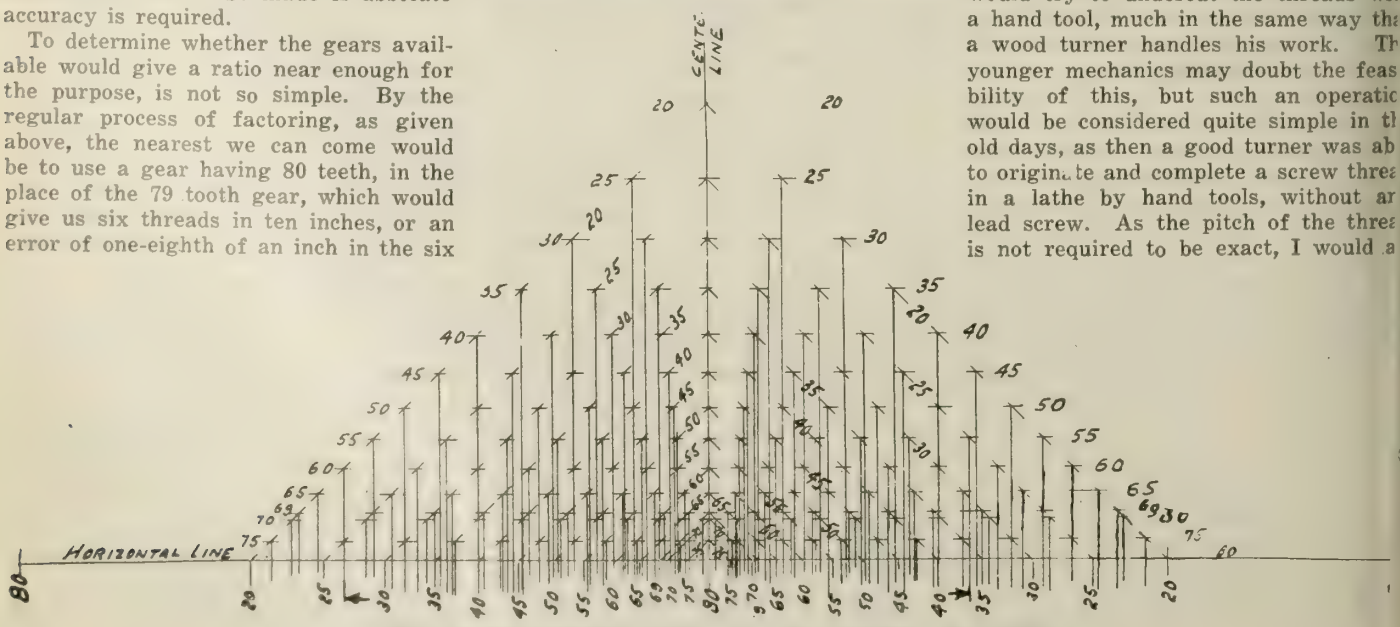
that is, the two driving gears will have 50 and 79 teeth, and the driven gears 20 and 30 teeth respectively. All of these are available except the 79 tooth gear which will have to be made if absolute accuracy is required.

To determine whether the gears available would give a ratio near enough for the purpose, is not so simple. By the regular process of factoring, as given above, the nearest we can come would be to use a gear having 80 teeth, in the place of the 79 tooth gear, which would give us six threads in ten inches, or an error of one-eighth of an inch in the six threads. As the thread projection is little more than one-eighth thick, this error would be too great.

Although we cannot find a nearer ratio by factoring, we cannot prove that the gears given will not combine to give us a ratio near enough for our purpose. On the other hand, to determine the nearest approximation that we can get by working out all the possible combinations is a formidable piece of work, as fourteen gears used to give two reductions will make precisely 1001 combinations.

Fortunately this is one of the many problems, that can be solved by graphic arithmetic in a much shorter time than by any other method, and is another proof of what I am often contending, that graphic arithmetic is a science that will well repay its study and practice. However, to return to our problem. I find by adopting the method which I will outline later; by using driving gears having 60 and 55 teeth, and driven gears having 20 teeth, we get a ratio of 6.6, and that this combination gives the closest approximation possible with the change gears available. These gears will cut 6 threads in a length of

$$\frac{6.6 \times 6}{4} = \frac{39.6}{4} = 9.9 \text{ inches.}$$



or an error of only .015 inch, which is amply near enough for the purpose.

While it will be possible to machine these rolls by this gearing, the work is difficult to perform, and will take a good mechanic a considerable time to finish one, because of the difficulty of withdrawing the tool at the end of the cut quickly enough, reversing the lathe, and bringing the tool back again to its cutting position. There are only seven threads in the length of the roll, and most of the time will be spent in manipulating the carriage, and reversing the lathe. If there could be a portion of the collars on the ends of the roll cut away to permit the tool to pass through them the work would be much facilitated, but even then the lathe has to be reversed after only seven revolutions, and it will keep the operator jumping to make an kind of an output.

If there are any quantity of these to make, it would be much more economical to make a metal pattern, and have the thread loose on the pattern, which would of course be split. The molder would then withdraw the body of the pattern from the mold first, leaving the loose threads in the sand, and withdrawing these threads later by revolving them in the sand one half turn. This would permit making the casting with the thread undercut, and eliminate the necessity for awkward machine work.

### Use the Hand Tool

If the castings are already made, would try to undercut the threads with a hand tool, much in the same way that a wood turner handles his work. The younger mechanics may doubt the feasibility of this, but such an operation would be considered quite simple in the old days, as then a good turner was able to originate and complete a screw thread in a lathe by hand tools, without any lead screw. As the pitch of the thread is not required to be exact, I would a

THE AUTHOR SUGGESTS THAT YOU USE A CHART AS SHOWN.

ıost be prepared to guarantee that I now men who could chip the undercut ut, and make a good job of it, in less ime than by any machining process posible, but, alas, these men are getting ery scarce now, and the most simple perations have to be executed by mahine, no matter how long it may take.

Returning to the working out of the ears. The set giving the closest aproximation was worked out by the use f the figure accompanying this article, nd as the construction is simple, and has wide range of applicability in gear rive problems, it is worth while studyıg its principle.

The problem to be solved is this. Givn a set of gears, having from twenty to ighty teeth, advancing by five, and one f sixty-nine teeth, which combination ill give the nearest ratio to 6.583. To olve this it is necessary to know all the ossible ratios.

The figure is based on the following roposition:

Let a and b = the number of teeth in he driving gears.

Let x and y = the number of teeth ı the driven gears.

Then $\frac{a}{x} \times \frac{b}{y}$ = the ratio of the gears.

Therefore (log a — log x)+(log b- g y) = logarithm of the ratio.

Starting from the center line lay off n both sides, on the horizontal line, he logarithm of eighty to scale. From he outer ends of this line, mark off oints at lengths equal to the logarhms of 25, 30, 35, etc., up to 75, doing is on both sides of the center line.

This is equivalent to taking the logarhm of 80, and graphically subtracting om it the logarithms of the various mbers, 20, 25, etc. It naturally folws that the point 40 for example, on left hand side, is distant from the nter line a distance equal to log 80 — g 40, which in turn will be equal to the g 80/40 = the log of the ratio of that air of gears.

Similarly, on the right hand side of e center line, it is obvious that the disce from the center line to, say, point is equal to log 80/30, or the logarm of the ratio of a pair of gears hav- 80 and 30 teeth. It follows then at the total distance, between these o points, measured horizontally, is al to the sum of the logarithms of the o ratios, and is therefore the logarm of the product of these two ratios, e the logarithm of the ratio of the pairs of gears combined in a double rtion.

From each of the points so found on horizontal line, we draw parallel gonal lines, meeting at the center line, through their intersections with the nter line horizontal lines which are mbered to correspond with their reective diagonal lines, as shown. A gonal line from point 80, is not shown, it is not necessary, but it will be apıarent that the lengths of all the horizontal lines, if produced out to this diagonal, would be equal to the logarithms of their respective numbers.

Just as the points on the lowest line represent the ratios (by their logarithms) of each pinion to an 80 tooth gear, so will the corresponding points, on the other lines, represent the ratios of the same pinions, to the other gears, having 75, 70, 65, etc., number of teeth.

The intersection of any diagonal line, and any horizontal line, must be distant from the center line a space measured horizontally equal to the logarithm of the ratio of two gears having a number of teeth, corresponding to the numbers on these lines. If we now drop vertical lines from each such intersection, we have graphically the logarithms of all the possible ratios, given by the distances from each vertical line on one side of the center line to each vertical line on the other side.

Taking a pair of dividers, set to the length corresponding to the logarithm of the desired ratio, namely, the logarithm of 6.583, we pick out the pair of lines whose distance apart comes nearest to being that distance, which are the pair marked by arrow heads in the figure.

Following these vertical lines up to their intersections, we find on the left that we have the choice of either 75 and 25 teeth, or 60 and 20 teeth, and on the right, we get 55 and 25 teeth. As we have only one gear of each size, we take the 60 and 20 for one pair, and the 55 and 25 for the other pair.

## SPRING COLLAR HOLDS GEAR IN PLACE

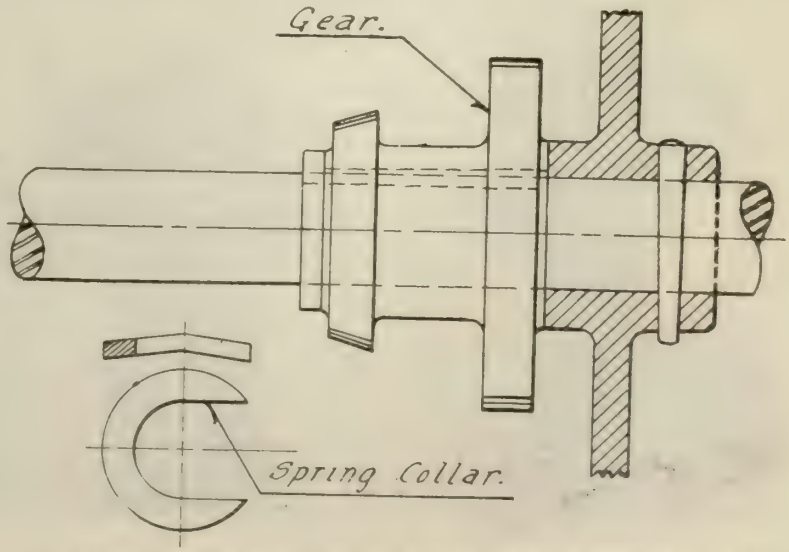
By F. H. M.

For holding a gear in place on a long shaft where it was necessary to remove the gear quite often a spring collar such as is shown by the accompanying illustration was used to good advantage.

This gear is a slip fit on the shaft and a square key drives the same. The shaft has a groove cut around or in it and the collar shown is slipped into this groove, the collar bears against the gear hub, thus retaining the gear in position on the shaft.

In making this collar it is bent slightly in the manner indicated and hardened and tempered in that position, thus it has a little spring to it which causes a slight tension on the gear and prevents rattle.

## SCREW CUTTING QUERY

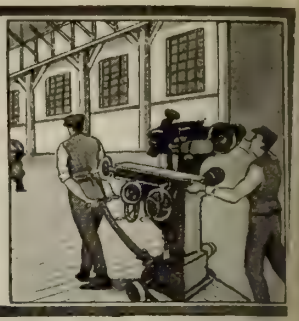


By H. R. J.

The question on screw cutting, which appeared on page 74 of the May 5 issue, is somewhat out of the ordinary but may be solved by the same method used for common threads—to a close degree of accuracy. It was shown that the pitch was 1.6458 inches, so that with a four-thread lead screw the ratio would be as .25 to 1.6458. It will readily be seen that the lead screw must revolve much faster than the work, so that the driving gears will require to have the greater number of teeth. It is also obvious that a tooth more or less in a large gear will make less difference in pitch cut than a tooth more or less in a small gear. For the problem in question (a four-thread lead screw and gears as stated) a suitable compound train would be 75 into 30 and 92 into 35 —the 92 being the new gear required, the two large gears being the drivers.

To prove the accuracy of the train, divide the product of the driving gears and the lead screw by the product of the driven wheels. Thus:

$$\frac{75 \times 92 \times .25}{30 \times 35} = 1.6428 \text{ inches.}$$



This is an error of 1.6458 minus 1.6428 equals 0.003 inch per pitch of screw, but only 0.018 in six complete revolutions. As absolute accuracy does not seem to be required, this discrepancy could be taken up by manipulating the compound rest.

METHOD OF HOLDING GEAR ON SHAFT WITH SPRING COLLAR.

# DEVELOPMENTS IN SHOP EQUIPMENT

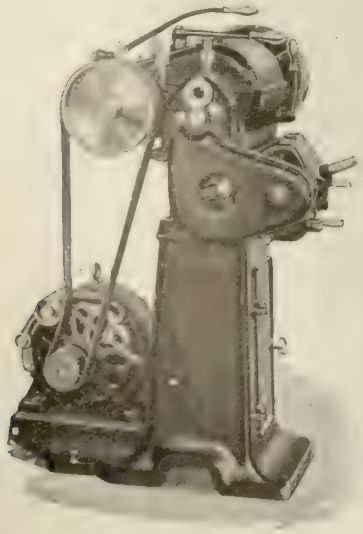
## QUICK CHANGE LATHE

The Rockford Lathe & Drill Co., Rockford, Ill., have placed on the market a 14-inch swing, motor driven, geared head, quick change lathe as shown in the accompanying illustrations. This machine is intended to meet the demand for a small heavy duty lathe of sufficient weight and power to handle rapid production.

The bed is of deep cross section and is well braced. The headstock is driven by a single pulley running at 400 r.p.m. Twelve spindle speeds are provided in geometrical progression with the use of only 13 gears. These are of large diameter, wide face and coarse pitch, are cut from solid steel and run in continuous oil bath. Spindle and all shafts are of high carbon steel, accurately ground to size. Spindle has 1 5/16-inch hole through its entire length and is provided with special thrust bearings of alternate collars of hardened steel and bronze. All bearings are of high grade bronze and are equipped with large, sight feed oilers.

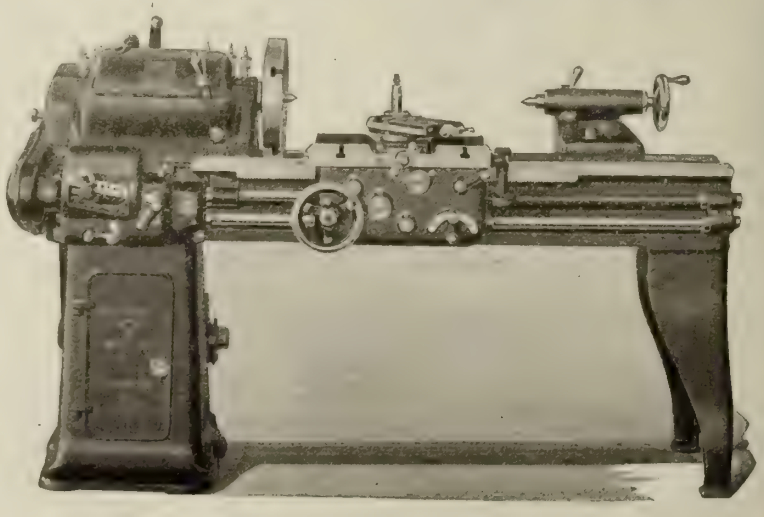
The tailstock is of the off set type, allowing compound to set parallel to bed and is provided with set-over for turning tapers. Tail spindle is locked by a new and improved clamp which does not require the barrel to be split.

The carriage is especially heavy, with extra wide bridge, and has a bearing on the ways of 20¼ inches, being provided with self oiling felt wipers. A thread cutting indicator enables operator to catch any pitch of thread without reversing lathe.



The quick change gear box is of new design, a simple and powerful unit having 32 changes of threads and feeds obtained through sliding steel gears and hardened steel clutches, controlled by two large convenient handles in connection with tumbler. Direct reading index plate mounted on front of box gives standard threads from 4 to 56 and feeds 18 to 252 per inch without the removal of any gears, but special pitches may be cut by substituting extra gears on the quadrant, giving an almost unlimited range. All gears are of wide face and coarse pitch and are cut from solid steel. Lead screw and feed shaft operate independently, either being engaged by knob in front of box.

The motor may be of any standard make, using either direct or alternating current, preferably of 1½ or 2 h.p., with constant speed having a maximum of 1,200 r.p.m. Motor is mounted on detachable plate securely fastened to base cast integral with cabinet leg, driving through a long belt 3 inches wide, kept at the proper tension by means of an adjustable idler pulley. This construction eliminates the task of removing motor should occasion arise to lift cover of headstock for inspection or adjustment. Lathe may be furnished with or without motor and is regularly supplied with cabinet leg as shown on cut. In some instances, motor may be placed on the floor, wall or ceiling and belted direct to headstock pulley, in which case idl pulley may be omitted as the belt te sion may then be taken care of by t usual motor base and adjustable rai When this arrangement is desired t ordinary leg is substituted for cabir leg.



The regular equipment includes stea and follow rests, large and small fa plates and wrenches.

## LATHE TOOLS

Several new designs of lathe to s have been placed on the market by M. . Hill, 10 Eden Street, Worcester, Ma . These include a boring tool, a thread g tool, and a lathe test indicator. In e boring tool the bar is held by means f a swinging link that permits of vert l adjustment of the tool bit without al - ing the alignment. One single sc w provides facilities for tightening the .r and the holding link. The design of .e threading tool provides for its use eit r as a spring or a rigid tool. The cu r blades are interchangeable and are ad justed by means of a vertical screw s back of the cutter. The conversion o the tool from a rigid to a spring too is by means of a tapered bolt passing tr s versely through the shank. The l test indicator is fastened to the shan a universal joint, thus permitting e ready setting to any angle. The to provided with two sensitive points m either of these may be removed wit disturbing the other. Facilities are provided for easy access to the int for repairs or adjustment.

END VIEW OF MACHINE.

GENERAL APPEARANCE OF THE LATHE.

# NEW THINGS IN MACHINE TOOLS

### PUNCH AND RIVETER

The Band Pneumatic Tool Co., Kansas City, Missouri, have designed and developed a new punch and riveter.

Among the advantages claimed for this machine is the fact that although it is a standard unit it weighs but 750 pounds and can be readily moved from place to place in the plant where the work to be done is located. The air cylinder is of the single type and connected to the plunger by means of a heavy lever, the fulcrum point being so located as to give the maximum tonnage on the rivet dies. The frame is of single section, split head type, one piece, of high quality cast steel. The air cylinder piston head and cylinder head is of gray iron. Piston head provided with lever cups held in place by follower rings. The air cylinder head is provided with a stuffing box and nut, properly backed to prevent leakage around piston rod. Bosses are cast integral with outside base surface of air cylinder, providing proper connection through bolt with rear end of yoke, giving the air cylinder a knuckle joint motion. The fulcrum lever is strongly constructed of cast steel. The valve is equipped with foot pedal control, leaving both hands of the operator free to handle the production as it passes through the machine.

The machine has a capacity for punching 13/16-inch hole in a 9/16-inch plate and a riveting capacity of ⅜-inch cold rivets. It is operated on a standard air pressure of 100 pounds and exerts a pressure of 70,000 pounds on the rivet and punch dies. In a recent test this machine with two operators did the work heretofore accomplished by eight men using pneumatic hammers. It is said to be especially adapted for light structural steel work where mass production is desired and rigid fabrication essential.

### SELF-CENTERING CHUCK

A chuck operated by worm gearing in connection with a scroll plate has been developed and placed on the market by H. Spillman, of Zurich, Switzerland. The scroll proper is not an integral part of the plate, as is usual in chucks of this nature. The scroll is so designed that but one tooth of the jaw is engaged at the one time, with the exception of the small overlap given to the scroll. This construction makes it possible to give a shape of the jaw teeth that will add greatly to the bearing surface in contact and also to the efficiency of the chuck. The scroll is very heavy, is let into a groove in the plate and is hardened and ground. The jaws are of steel, hardened and ground.

### ECONOMIC TOOL HOLDERS

That "good tool holders are not an expense, but an investment" is the point emphasized by the Canadian Production Tool Co., Walkerville, in describing the merits of their new line of tool holders. These are made of tool steel, and slotted in such a way that turning bits of any length may be easily adapted to the job. An economic feature of this idea consists in the fact that broken or worn drills or pieces of high speed steel that can in any way be used as a tool may be converted into a valuable bit. A variety of designs have been followed in the holders, rendering them adaptable to any requirement. The straight shank holders are the best for heavy duty work and will stand up under exacting service. This tool has a round socket to permit of bits of any length being used. A right or left hand square turning tool holder is designed to utilize scrap high speed steel of any length. A right and left hand square turning tool holder without cap screw is adapted to work when it is necessary to have the holder and tool close up to the work, permitting heavy cuts at high speed without chatter. An economical holder is the right and left hand round turning, without cap screw. Time can be saved in not having to tighten and loosen the cap screw as the tool post screw will efficiently serve the purpose. A broken or worn drill is just as useful in this holder as a standard bit. The line includes right and left hand cutting off holders with or without cap screw, double and single blade parting tools, straight round turning tool holders, drop head wheel lathe tool holders and straight cutting-off tool holders. It is difficult to imagine a purpose in tooling to which these holders are not adaptable and the outstanding claim for them is that they pay for themselves by converting into actual value material that is very often regarded as waste.

### TWO-SPINDLE THREADING MACHINE

Some interesting features are incorporated in the new two-spindle threading machine recently brought out by the Geometric Tool Co., of New Haven, Conn. External or internal threads may be cut by using taps or dies in the heads, and several combinations of threading are possible by the use of the two heads. The drive for the two spindles is obtained through the one single pulley at the rear of the machine but each spindle may be controlled independently by means of the change gear levers located at either side of the machine. The opening or closing of the dies or taps is controlled by adjustable stops. Accurate setting of the work for length of thread is secured by means of suitable gauges. The machine, if desired, may be fitted with ball-drive reversing tap holders. The machine has a tapping range from ⅛ inch to 3 inches.

## Ideas for Stimulating Interest

IT is a well-recognized fact that employees could, if they so desired, save many a dollar for their employers, but how to get them to make their suggestions is another question. In speaking on this subject, "Factory" tells the following story:

"An Eastern manufacturing company failed to get good results from their men through the suggestion boxes. Although they reorganized the committee handling the suggestions, and in every other possible way endeavored to get the men to make suggestions, still they were not successful.

"The prizes offered were cash payments and the company did not hesitate to pay well for good ideas. Yet all was to no avail. Finally the matter becmae such a drag that it was brought to the attention of the factory manager.

"He started out to make a detailed analysis of the problem and before he had gone very far he learned that the main trouble was due to the fact that the foremen were doing everything possible to get new ideas from skilled men, such as machinists, but were paying no attention to the semi-skilled and unskilled men. The situation had become so acute that the factory manager found most payments had been made to a few men who had been christened, by the balance of the employees, 'Suggestion Hoppers.'

"This opened his eyes and thereafter in each man's pay envelope there was a little slip telling a man how much more he would have had in his envelope if he had made a suggestion.

"For instance, one slip read: 'You lost the price of a new pair of overalls this week. Why? Because you did not turn in a suggestion.'

"After a four weeks' campaign of this nature there was literally a deluge of good suggestions. All this due to the fact that every man in the ranks was thinking, instead of just a few."

## Industrial Fatigue

THE subject of Industrial Fatigue was the title of a paper delivered recently before the Royal Society of Arts in London, England. It was pointed out by Dr. Myers, the author of the paper, that five different factors are involved in the problem of quantity production; namely, fatigue, practice, incitement, settlement and spurt. In commenting on the paper, "London Engineering" says:

"Dr. Myers showed some curves illustrating the effect of hours on workers, comparing the eight and ten-hour days and stated in his paper that the reduction in hours increases almost invariably the hourly output. Although there are, and have been, undoubted instances where this has occurred, there is, in our opinion, need of much further data before this rule can be laid down. The lessons of the past two years certainly in many directions are in conflict with the contention. Hours have been reduced 20 per cent., but output has fallen by a good deal more, in spite of many efforts to make the conditions of the employee more pleasant while at his work, and to assist him in enjoying his leisure in a healthy way. There must obviously be a limit, and who shall say definitely when we have overstepped it? After a few years of eight hours we will be told probably that output will increase if we reduce the hours to six; a spell of that and then the demand will be for four, which some labor idealists are dreaming of now. From present indications it would appear that the maximum output is to be obtained with something over eight. Even Dr. Myers' curves were by no means convincing on this point. In fact, when the classes of work were differentiated, it seemed to us in the short time the curves were to be examined on the screen that in some processes the ten-hour day seemed the more productive."

* * *

## Developing Export Business

TO develop a successful export business it is essential that the manufacturer provide adequate facilities in the new field for supplying the immediate needs of the prospective customer. The possibility of several weeks' delay in delivery of goods has frequently resulted in loss of business. The display of merchandise that can be disposed of on the spot is a necessary factor in creating and holding new markets. In a recent issue of "Machinery" appeared a brief statement—in the form of a suggestion—from Col. W. N. Taylor, European sales manager of the E. I. DuPont de Nemours Export Company, of Paris. He says:

"To solve this problem the only method at present is for each individual manufacturer to undertake the maintenance of a storehouse, but in many cases the overhead involved is prohibitive. It would be of interest to members of the American Chamber in France to consider the possibility of a number of houses forming a small company to maintain a warehouse, with a truck or trucks, for deliveries and for handling the stocks of the member companies. This would permit companies carrying a moderate-sized stock, or who are uncertain as to their proper stock volume, to enjoy the facilities of a stockroom, with access to and control of their merchandise in a manner more satisfactory than as at present in public warehouses."

* * *

## Trans-Atlantic Wireless 'Phones

IN a recent issue of the "London Times" appears a statement by Marconi, relative to the demonstration of long distance telephony carried out by Col. Varty in the United States. Mr. Marconi's ideas on this subject were, in part, as follows:

"It is a great achievement as far as ordinary telephony goes; the wireless part is only twenty-nine miles. That is nothing. If it had been 2,900 miles it would interest me. The demonstration is said to prove it is possible to telephone—by wire, of course—from London to India, and perhaps to the Cape. I say that it is quite true, but you would have to overcome the difficulties of maintaining a telephone wire of that length. If the wire were to South Africa it would have to go through France and Spain, across the Straits of Gibraltar and along the whole of Africa to the Cape. I do not think that is practicable in the present state of the world.

"The alternative is the wireless telephony that has been developed, but I do not think it is at present capable of doing these very long distances, although a few words have been gotten through from England to America and from America to France. Since ordinary telephony will not work through long cables, this achievement in America doesn't bring a solution of the problem any nearer, so far as telephony across the ocean is concerned. I expect to bridge the Atlantic with wireless telephony and I think—though one cannot always be certain—that the ocean will be bridged first in a practical manner by wireless telephony, and not by telephony through a cable. The cost of laying a practical telephone cable between Europe and America would be prohibitive."

## Development of Copper Steel

"IT is estimated that the annual wastage due to corrosion of iron and steel products is between 60 and 90 million dollars, this being the bare cost of the materials lost without taking into account other closely allied losses. During recent years the problem has been attacked from many different angles, but in the light of present knowledge, considering the average materials of construction, it is considered that the best results are obtained by alloying from 0.15 to 0.30 per cent. of pure copper with normal Siemens or Bessemer steel. Material of this nature has been on the market since 1911."

So states D. M. Buck in "Blast Furnace and Steel Plant," and the following information on the subject is quoted from various papers published over a number of years. Copper in soft Bessemer steel lessens corrosion. Copper steel resists the action of sulphuric acid. Bessemer and open-hearth steels containing 0.15 to 0.30 per cent. of copper show decided superiority against corrosion under actual service conditions. The corrosion of electrolytic iron is reduced if it is alloyed with various amounts of copper, nickel and manganese. The durability of old steel fencing wire is due to the fact that it contains copper. Steel with as little as 0.03 per cent. of copper corrodes only 60 to 70 per cent. as fast as steel containing 0.01 per cent. The minimum copper content from the point of view of resistance to corrosion is 0.15 per cent., and it is not necessary greatly to exceed this figure. The life of unprotected steel sheets having a copper content of 0.15 to 0.25 per cent. is increased from 300 to 500 per cent., while the increase in cost over plain steel is not more than $2 to $3 per ton.

While most iron and steel fittings used in exposed positions are, in most instance, provided with some sort of protective coating, this is generally only of a transitory nature, and as soon as it wears off the bare metal is subject to corrosion. If the metal were copper steel, the extra life would be an asset of incalculable value. It is also claimed that when copper steel is painted the adherence of the paint is much better than on ordinary material, so that this protective coating remains longer in position, and so adds further to the durability of the material as compared with ordinary steelwork. The claims of copper steel are fully substantiated, while the low melting point of copper ensures its rapid diffusion when added to molten steel, and it does not segregate.

## Keeping the Plant Running

WE hear a lot about hard times, poor business, and hard luck, in the United States, but in a recent article in American Machinist, an eastern manufacturer unloads himself of some splendid optimistic remarks. He states as follows:—

"These are ideal times to push new developments whether in machinery, tool design, method of work, or improvement of shop processes. Such work is of a nature to be day-work rather than piece-work, and to require almost the entire payment in the form of wages rather than material as compared with regular production work. The available resources can be used to carry the organization a longer time, at the same time producing results which will give a big boost to the production business when the demands for that again return.

"Our principal task is to maintain our organization. We plan, instead of laying off a certain percentage of men, to run the whole shop a certain percentage of the time, so that the entire organization may be carried along. Reduction of overhead expense is taken for granted, but this entails close supervision.

"While we are building some complete machines for storage, there are objections in connection with the income and excess profit taxes to this that set a limit to the practice. A given amount of labor and material will show a higher inventory value in finished machines than in any other form. This means a higher book profit at the end of the year, and a higher tax, even though not a machine is sold.

"We have no immediate expectation and do not think it will be necessary to reduce wages. The machinist has been poorly paid as compared with some of the organized industries and we believe that he should not suffer because he is unorganized."

## Two Methods of Saving Nails

NAILS, like matches, are very seldom considered an expensive item. At least, from the amount of nails and matches wasted, one could quite readily come to such a conclusion. A writer in Factory, speaking on the subject of nails, comments as follows:—

"After the steel strike the price of nails went sky high. The superintendent of a Connecticut factory found it difficult to get a supply sufficient for the every-day needs in the factory.

"By a little careful planning he was able to effect quite a saving of nails in the box and case department. All of the wooden boxes and cases are used for shipping purposes. So the number of nails to be used in the different widths of boards was standardized. Heretofore five or six nails were used in a board where four would have been plenty; or four nails when two would have been sufficient.

"The same method of procedure was carried out in the shipping room. They now use only enough nails to nail up the shipping cases properly. The superintendent prevailed upon the shipping clerks to keep within the standards set, and the results are gratifying.

"In the carpenter shop they are also conserving their nail supply by applying common sense to the use of nails. When the carpenters get through with a job anywhere around the factory there are always a lot of nails left scattered about the vicinity of the work.

"Some are perfectly good, others bent or blunt. By using a large magnet they can easily and quickly gather up the loose nails. These are sent to the gate house, where the gate man in his spare time sorts and straightens out the bent ones.

"All in all, they are saving a lot of nails in the factory every day; and, what is equally important they are effecting this saving almost without cost."

* * *

## Directing Power Into Useful Work

IN considering the question of power and its application to the machinery which it is to drive, we are confronted with a rather complex subject. So states H. Campbell in the "Michigan Manufacturers' and Financial Record."

"The last few decades," he continues, "have seen the development of the belt drive, and by far the greater amount of machinery, especially that used in production of small metal parts, is belt-driven. The use of the chain is coming more into favor, also, as a result of recent developments in chain-belt engineering. It is often exceedingly useful for transmission of power within the limits of a single machine, and beyond a doubt will be applied to many new uses in the future.

"The respective advantages and disadvantages of these methods depend upon the conditions, size of the machines to be operated, and the duty that is to be performed. Where the amount of equipment to be driven is not too great, the economy of driving direct from the lineshaft is apparent. But where the volume of equipment is so great as to necessitate the division of the plant into several departments, the problem is solved by the use of electricity. In this case, all the machines which would be most likely to be in operation at one time are grouped together and a motor supplied for the group. And very recently a number of plants have been built in which the individual motor-driven system was adopted, thus eliminating the problem of belts, shafts and countershafts, with all the attendant accessories.

"A recent survey of the methods of power transmission employed by American manufacturers has disclosed the fact that 78 per cent. use belting (or rope) in their plants. Of this number 48 per cent. use leather belting and 24 per cent. use rubber belting. The silent chain has gained favor rapidly in the last few years as a medium for power transmission.

"The pulleys in general use are the wood, iron, paper, and leather, and an iron pulley surface with hard maple wood.

"Bearings are now either the roller or the ball-bearing type, although a few bronze and babbitt bearings are still in use."

# What Business Paper Editors Say of the Outlook

## A Decided Undertone for Improvement

By J. L. WYCKOFF,
Editor "Canadian Grocer."

WHILE sales are still from ten to fifteen per cent. less than normal, viewing the business situation from the wholesale grocer's angle, there is a decided undertone for improvement. Last year wholesale merchants failed to see the hand writing on the wall and the mad scrambling to stock up that was manifest since 1914 continued until well into the fall of the year. Buying for future was the order of the day, undoubtedly more from force of habit than from lack of judgment and foresight.

When the markets commenced to sag some wholesalers still continued to buy futures. Take the case of prunes, for instance. The opening price on prunes was several cents per pound higher than in 1919, but in spite of this and the fact that other commodities were due for a landslide, heavy purchases were made. Some houses found themselves with as much as two cars of prunes on hand when the market broke. The downward movement on prunes continued until as much as seven cents per pound decline was registered on some sizes and around four cents on others. A car of prunes will average 30,000 pounds, so it is an easy matter to estimate the loss on this one article. But prunes was only one item; rice, canned good and dozens of other lines were equally hard hit.

One wholesale merchant recently told the writer that during the past year they wrote off $33,000.00 on their inventory. This firm takes stock twice a year. On the first of November lst $20,000 was deducted from the inventory and on the inventory just completed May first, the slate was further wiped to the extent of another $13,000. This was not done with the expectation of lower levels, but in order to bring their stock in line with present values.

Other wholesale houses have been doing the same and it is safe to say that the loss will average four per cent. and the loss in Toronto alone will run into half a million dollars. Keen competition, and in many instances selling goods at a less price than replacement costs, has resulted in fairly well cleaning up stocks, and no doubt will be the means of bringing about a more rapidly stabilized basis.

The fact of the matter is that the buying last year was unduly heavy and prices unquestionably too high. Something had to happen, and it did with heavy losses. This year wholesalers are not buying futures and intend to carry out this policy for the balance of the year at least. This will probably result in short packs, but perhaps, commendable, as it will tend to create a more active, sane movement.

## Farm Business Conditions

By F. M. CHAPMAN,
Editor "Farmers Magazine."

THE farmer's period of deflation has arrived. Tumbling prices for all his products have left him almost dazed with the giddy decline. All livestock have followed, although not so disastrously, the lead given by sheep and wool. Many feeders this past season have lost heavily in their sales of beef cattle. Some even were unable to repay the bank loans from the sales. Pork is down to a point where profits seem questionable. Following this, comes the fall in the prices of all coarse grains. Wheat has dropped to near the dollar mark. Oats and barley are below pre-war prices.

Poultry and dairy products have also declined to an extent which seemed impossible two months ago. Butter, despite the smaller cold storage returns, of over 500,000 pounds in the U.S. over last year, has been selling for 22 cents at country points, while one cheese board last week reported no sales with a quotation of 14 3-4 cents.

Nevertheless, farm operating expenses have declined nothing like these figures. Wages made at the beginning of the year are still high. Farm machinery has even advanced so that there is the unmistakable evidence throughout the country for farmers to stop buying beyond immediate necessities. It is noticeable though, where commodities are cut in prices with an evident desire to meet the drop in farm products, that there is a tendency to carry on in their purchases. An instance of this is seen in the paint business. Early price cutting by manufacturers induced many people to go ahead and apply the paint that was long overdue although this was hampered somewhat by the high retail prices on old stock.

Seeding has been done in Canada under fairly favorable conditions and the outlook for crops is so far a good average one. The usual enterprise in feeding cattle is not in evidence as livestock are a debatable question at present. The American tariff and the likelihood of the British embargo remaining on, are not encouraging agriculture for her future markets. High freight and express rates are having a most depressing effect on agriculture generally, for the returns to the farmer for his produce, after deducting freight and commission charges are so much lower that profits are entirely forgotten in farm business. Naturally then the farmer's buying power must be seriously interfered with.

The farmer is saying very little about it. He has not complained about the drop in prices. He is sitting tight waiting for others to do likewise and if he does not buy, business in Canada will certainly feel the jar. It is felt that a return to normal prices in labor as well as in commodities would encourage greatly the production of wealth, and a greater circulation of money during the coming fall and winter.

## Stocks Are Getting Much Depleted

By H. L. SOUTHALL,
Editor "Hardware and Metal."

WHILE wholesale hardware trade has been maintained in good volume during the first months of this year, little booking is being done for future delivery by the retail trade and some wholesalers fear a continuation of quiet trading during the summer months. On the other hand the retail trade has been ordering goods only as required, and generally frequent orders for small quantities, and if this policy continues the volume of summer trade may show up a good deal better than expected. Wholesalers are liquidating stocks in most seasonable lines in the expectation of lower prices before these will again be required, but on lines which are in demand all year round a normal stock is being maintained.

With retail hardware merchants reporting active business especially from the farming communities in Eastern Canada one prominent wholesale merchant is of the opinion that underlying conditions in the retail trade must be better than at this time a year ago, even if there is little evidence of improvement. He is of the opinion that retail stocks must be getting pretty well down to the shelves, and that the law of demand must soon make itself felt. Some wholesalers and manufacturers are of the opinion that a stimulation of export trade would materially help present conditions.

It is significant that hardware trade in manufacturing centres is feeling the pinch more than in the rural districts. Recent legislation affecting firearms and ammunition has curtailed trade in these lines, and some changes in prices of binder twine, etc., may be necessary, due to the increased taxation provided under the new budget.

Generally speaking, manufacturers and importers of hardware expect little change in prices due to the revised tax and tariff regulations, which add approximately 5 per cent. on U. S. goods imported into this country. The effect of the changed basis of value for duty may affect Belgian windo

## Must Act Quickly Now

THE charge has been made several times that Canadian firms are not very keen on following up chances to open accounts. Those who have had experience with Canadian business methods abroad find fault with them in many cases, and charge that strict attention to mail and requests for information would be the means of helping to secure quite a lot of business that is going elsewhere.

The purchasing agent of a manufacturing concern in Canada told a representative of Canadian Machinery of an experience his firm had in the last few weeks. They were in the market for a large quantity of work, as their business in this country is largely an assembling proposition, although the parts, in the great majority of cases, are made in shops in this country.

Recently a request was sent out asking for firms that were interested in doing certain parts of their work to make the fact known. It was not a small piece of business, either, but one that would keep a good many shops running comfortably for a spell.

The letter was sent to six firms. On the day following a wire was received from one firm saying that their salesman would arrive on the first train. The purchaser at once thought he was going to have a procession of salesmen at the plant, and get their wants attended to at once.

Four of the firms replied on the fifth or sixth day, and they each stated that they could handle the work if the firm in question sent on the blue prints and allowed them to figure on them.

The sixth firm has not been heard from yet, according to information received a few days ago.

The firm that sent up a salesman the day following the receipt of the letter received a sample order and is having it done in his plant, and the chances are that he will land a good deal more of the work, provided he can do the work to the satisfaction of the customer.

Business is for the man who is after it hard at present. There are very few orders being placed on platters and carried in just now.

## A Possible Solution

THE composite ton of steel was worth, at last reports, $43.05. By this is meant the average price of a ton of pig iron, billets, slabs, sheet bars, wire rods, steel bars, plates, structural shapes, black, galvanized and blue annealed sheets, tin plate, wire nails and black pipe. In February it was $48.81, and in March of 1920, $68.66. In May of 1914 the figure stood at $22.99.

Judge Gary, of the United States Steel Corporation, in annual report to stockholders, recommends as a possible solution of or antidote to labor union problems, publicity, regulation and reasonable control through Government agencies. Both organized capital and organized labor should be placed under these regulatory laws. Each should be entitled to the same protection, and be subject to the same restrictions and provisions.

It is significant, says Iron Trade Review, that although hundreds of attempts have been made to place the direct reduction of ore to finished steel on a commercial basis and more than 70 "direct" processes are known, none of these methods, in recent years at least, have been formidable competitors of the conventional process involving the blast furnace and steel melting furnace.

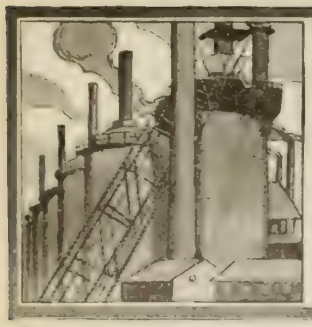
Produce cheaper and produce better than you have ever done before is the solution of the present situation. No easy matter, we know, but there is no other way out. To a very large extent this is a price market at present.

## Important Iron Discovery

SHOULD first reports be true of the recent discovery in the Cobalt district, Canada has added another important link in its industrial chain. It is claimed that the iron content is approximately 70 per cent., but it is more than likely that this figure will be found too high on more careful examination, as 70 per cent. iron is something not met with every day. In any case the presence of iron in mining quantities is very welcome, and the development of this new discovery will be watched with interest.

### WHAT BUSINESS PAPER EDITORS SAY

Continued from page 98



glass slightly, but this will not be a serious factor. German hardware will be affected to the greatest extent by this ruling.

The primary markets have been prominent when related to the production costs of the manufacturer, and declines in these have been felt in many hardware lines. Some marked changes to lower basis have been noted recently, among which are ingot metals; cordage and cotton goods; fuel and lubricating oils; solders, lead products, pipe fittings, corrugated sheets, Canada plate, waste materials, leather and harness parts, some lines of woodenware, tools, standard compression work, galvanized ware, ammunition, rule and level goods, range boilers and valves; boilers and radiators, pumps, etc.

Speaking of the popular sentiment that prices will soon return to pre-war levels, one manufacturer has the following to say:

"When we consider how anxiously everyone is now stewing around to try to determine whether the selling prices will go lower than in pre-war times, it causes one to smile when he thinks of the unanimous decision of all the wise ones that prices would never revert to old figures, because standards of living had raised to such an extent that people would never be satisfied to go back to pre-war prices.

"It is wonderful what a balloon will do in the way of collapsing if it is properly perforated."

# MARKET DEVELOPMENTS

## Buyers Purchasing Immediate Requirements Only

### Production of Steel in United States is About One-Third Normal —Demand Approximately at the Same Level—Wage Adjusting Continues—Pig Iron Dull, But Old Material Shows Strength

REPORTS from the steel markets confirm the idea that the present situation is one in which the buyers are pursuing a policy of "laissez faire." The general condition in industry is not what would tend to give much confidence, and what will satisfy the immediate requirements is about all that any consumer wishes to be burdened with. The usual period of dullness which comes in the summer months shows no signs of being lightened this year, but will more likely be accentuated. The production of steel in the U. S. is only about one-third of normal, and demand is at about the same level. There has been some export business booked by the Steel Corporation, about 11,000 tons of rails having been ordered for Japanese railways. There is also enquiry for rails for China, and Argentina is in the market for the same goods.

There is a good deal of wage adjusting going on in the Pittsburgh district, and this adjustment is all downwards, as would be expected. There are also signs that the automobile trade is about to enter on another quiet period, although the reductions in price which are promised for the end of June will perhaps have a stimulative effect on this trade.

The pig iron market remains dull for the most part, although there are some slight spots where a better business has been done. This has been in the line of supplying iron for special contracts, the prices remaining about the same as last week.

The old material market is stronger in U. S. centres, the steel grades showing better than the others. Dealers are stocking up their yards in the hope of realizing on a rising market, and this tends to keep prices firm.

Locally the demand for small tools and supplies continues to improve, and the market for structural shapes shows an upward tendency. Machine tools still stay in a comatose condition, but dealers generally are rather optimistic as to this market's immediate future.

## CONSUMERS CONFINE BUYING TO SUPPLIES FOR IMMEDIATE NEED

MONTREAL, Que., May 23.—Apart from the announcement here and there of slight betterment in business, the general tone is not one of promise for the near future. Dealers here now think that the coming weeks will be exceptionally quiet with very light inquiry. The warm weather and the holiday season will add to the dullness in industry, and prediction seems to favor a summer of quiet activity. Railroad shops here are again closing for a period of ten days, owing to business depression.

#### Dullness in Steel

"One feature of present inactivity," said a steel dealer here, "is the spasmodic buying that develops from time to time, and from many varying quarters. Just last week we had a fairly large order from a concern that has not bought for months. Everywhere we find that consumers are refraining from taking on any stocks and confine their buying to such supplies as will carry them over for the immediate present. In the light of clearing the decks of industrial plants this process is a good thing and should eventually prove beneficial and provide a good foundation for future construction, but it does not add to present activity." One dealer here reports some nice orders for wire rope. The plate demand in the district is almost nil, the railroads being quiet and shipyards doing only repair work. Steel production is said to be falling off and with foreign interests coming into the market it is not unlikely that the trade may see price declines in a short time.

#### Quiet Week in Machine Tools

District machine tool activity might be summed up in the three words, "very little improvement." There continues to be little inquiry for general supplies and for some lines of wood-working machinery, but the movement of metal working tools has shown no improvement. "We are entering a period which, in normal times, is credited with decreasing industrial activity, and it would not be surprising to see the next month or so featured by pronounced dullness in the movement of tools and supplies. The business now carried on is hardly sufficient to meet overhead charges, and very frequently the week will show a balance on the wrong side of the books. However, we still have hopes of a late summer revival."

#### Scrap Very Quiet

Complete absence of interest is shown by old material merchants, as there is little inducement to carry on business just now owing to the stagnant condition of the market. Little movement is reported and dealers with stocks on hand are reluctant to release material at prevailing figures, realizing that to do so would mean financial loss in many instances. "Quoting prices has no effect on the situation," said a dealer, "consumers are not buying on a basis of price, but only when they need scrap, and then the price is decided on according to the nature of the sale and the conditions involved. Almost any price might be quoted without awakening the

interest of buyers." What little movement is reported seems to favor the non-ferrous lines. Quotations on these are quite firm while steels are nominal.

## CONFIDENCE EXPRESSED FOR THE FUTURE

TORONTO, May 26th.—The spurt in business experienced by a few Toronto dealers and recorded in Canadian Machinery continued last week and is still being felt to some extent. Machine tools are quiet, also woodworking machinery. What activity there is is pretty well confined to small tools and supplies. This would indicate, as we have said before, a policy of hand-to-mouth buying. According to reports received in connection with a questionnaire sent out by Canadian Machinery to a number of metal-working concerns, business to date as compared with the same period last year trade is (on the average) about fifty per cent. below 1920. Considering that 1920 was an exceptionally good year this is encouraging. It explains the demand for necessities. The difficulty in making collections and the unsettled condition of things in general accounts for lack of buying on a larger scale. Dealers are sitting pat, picking up what business they can, optimistically awaiting the return of the buyer who even now is figuring on his requirements. One leading dealer expressed his confidence in the future and as evidence of his optimism outlined an aggressive sales and publicity campaign. Another dealer was of the opinion that a good deal of business could be done on long term financing, indicating that there is business in the background, but little cash to finance it.

**Steel Business Shows Improvement**

A report received by a Toronto house indicated a marked improvement in the market for certain lines of steel, largely accounted for by renewed demand by automobile manufacturers, and for structural steel plates. This condition has been reflected in the Canadian business of this concern especially in Ontario where considerable improvement was noted. Another jobber reported business in the mining district as fairly good, trade with other industries being very quiet.

Little change is noted or expected in the scrap metal market. Little business is being done.

## U.S. TOOL MARKET IS VERY DULL NOW

**Small Orders Only — Cranes Move In Small Lots — Cleveland Also Reports a Dull Season**

New York, May 26.—A dearth of demand prevails in the local machine tool market. Sellers assert there is no noticeable improvement in buying. The larger inquiries which have been reported, virtually all of which are from abroad, still are pending. Some buying by Cuban sugar interests of pipe fitting machinery and other equipment is noted, but this has been in evidence for several weeks and has not developed into business of special importance. However, in one or two instances some sizable buying is expected in the relatively near future. One is a list of approximately $100,000 of miscellaneous machine tools for a leading railroad in China, issued through the Wah Chang Trading Corp., 233 Broadway. Another is a list of equipment issued several weeks ago by the Japanese government for equipment for installation in its arsenals. Proposals some time ago were forwarded to Japan, and bidders are expecting a definite decision soon. A recent inquiry calls for a number of power presses for a Chinese mint. Domestic demand is comprised principally of inquiries for single machines.

Demand for cranes is listless. New inquiries are coming out slowly and orders are few. Sellers report several projects in prospect, but are not confident of business resulting soon. Recent inquiries include a 10-ton electric crane, with 47-foot span for the Foundation Co., 120 Liberty Street. A handpower crane of similar dimensions is specified as an alternate. A 15-ton electric crane, with 50-foot span, is to be bought by the Equipment Corp. of America. A 15-ton locomotive crane with 40-foot boom is being inquired for by L. B. Foster, 154 Nassau Street.

Cleveland, May 26.—Users of machine tools and equipment continue to confine their purchases to single units and repair parts. In the week just past demand even in this line was slack and dealers report there is little general activity other than that coming from the automotive trade. As yet orders and inquiries from the automobile industry are confined to single machines.

Prices continue weak although no new reductions have been noted. On the other hand dealers are known to be shading whenever necessary. A note of cheerfulness is reflected in the market, due to the better credit conditions. Dealers report bills are now being paid more promptly.

## POINTS IN WEEK'S MARKETING NOTES

**Inquiries are being made in the Buffalo market, asking for prices on quantities of iron for last half of the year delivery. This marks a departure from the policy which has prevailed for many months.**

**Scrap metal market at Pittsburgh shows a stronger tendency in the steel works grades. Some dealers continue to stock their yards in anticipation of a higher market. Trading is practically at a standstill at San Francisco.**

**Consumers are refraining from taking on stocks, confining their buying to immediate requirements. Some nice orders have been received for wire rope, and various enquiries have been made for general supplies, also certain lines of woodworking machinery. Metal working tools show no improvement, however.**

**One concern has announced the elimination of the eight-hour day and the substitution of straight time. This means roughly a reduction in wages of about 9 per cent.**

**The market for structural shops shows an improvement locally.**

**Small tools and supplies still continue favorable, but machine tools are rather inactive. Dealers in this latter line are, however, optimistic as to its future.**

**Consumers of scrap are not buying on a basis of price, but only when they need scrap. What little movement is reported seems to favor the non-ferrous lines.**

### RUSTLESS STEEL

According to the Vossische Zeitung, the Krupp works are paying special attention to the production of rustless steel, for which during the war there was an urgent demand as a substitute for platinum. The Krupp rustless steel contains a large amount of chrome, and is said to be remarkable for its hardness and strength. Its resistance to chemical influence is such that it is not affected by boiling nitric acid. One of the uses for which it is particularly proposed to apply it is as a substitute for nickel-plated metal in the manufacture of instruments. The firm is also studying the question of using rustless steel in the manufacture of plates for artificial teeth in place of the gold or vulcanite now generally employed.

### TWENTY-EIGHT YEARS' SERVICE

According to a statement made at the convention of the American Wood Preservers' Association, creosoted wood-stave pipes put in place twenty-eight years ago are still in perfect condition. The best method of treatment for the staves was described as being the empty-cell process with 50 pounds initial air pressure, following the creosote pressure period with several minutes' re-heating at about 25 degrees Fah. in excess of any previous temperature, then a vacuum of not less than 20 inches maintained for from 30 minutes to one hour. By this process a satisfactory creosote penetration is obtained, and the staves come out thoroughly clean, and so dry as scarcely to soil the hand.

# PRACTICALLY NO PRICE-CUTTING; STEEL PRODUCERS ARE NOT ALARMED

Pittsburgh, May 26.—Production of steel is declining at a slow rate. Measured by ingot output it was about 31 per cent. of capacity in April and is now a share below 30 per cent., while the indications are that a rate of 25 per cent, or less will be reached by July. That prediction is based on the fact that specifications and orders are coming in at a slightly lower rate now than a few weeks ago.

July is invariably a dull month in the steel market. Even in 1916, an extremely active year, the market was dull in both June and July, and this led to expectations in some quarters that the market would go off permanently, but it took a fresh start in August. Inasmuch as nothing good can be expected in July and we are only a few weeks from July now, it is regarded as certain that no definite improvement can occur in the near future. Predictions of improvement are now centering more definitely around the month of August, when a few weeks ago some predicted August, some September and some October. What is being predicted for later in the year is not a complete revival, but an improvement. Full operation of the steel industry is not expected before next spring at the earliest. It will be seen that if mill operations are 25 per cent. in July and become 50 per cent. in September, the 50 per cent. rate would be a very low one, but on the other hand it would represent a doubling in output, which would look very good. Before the war the steel industry had an idea that no combination of circumstances could put a demand to a point below 50 per cent. of capacity, and as a matter of fact there was never, before the war, an operation under 50 per cent. at any time. The capacity now, of course, is much larger.

### Attitude of Steel Mills

A notable fact in the situation, one that does not attract the attention it deserves, is the complaisance with which steel producers view the situation. They are not alarmed or perturbed or even particularly impatient. What is their philosophy? It is one that is common to the majority of business men today, that there must be a general and complete readjustment and that no one can expect real business activity until the adjustment is finished. Indeed, the philosophy goes farther than that, that no one should want a revival in business until the adjustment is completed, because such a revival would represent a false start, on an unsound economic basis, and there would be fresh trouble later.

Of course everyone would be much better satisfied if the readjustment should be completed suddenly, but it is recognized that it cannot be and men therefore are patient. An important point is that business men know, or at least are convinced that they know, just what they are waiting on, and they can read signs from day to day of how the readjustment is proceeding so that they can judge of the progress being made. There are various things needed for completion of the readjustment, but two things are picked out as the hardest and slowest and it is assumed that all the others will come around in ample time for these two, so that they are the ones to be watched.

These two are declines in retail prices commensurate with the declines in wholesale prices, so that the cost of living will be lowered by reasonable amount, and declines in those wage rates that are too high. When the readjustment started no one knew how far prices would decline or how far they ought to decline to produce a safe basis. Now, however, there have been such declines in some commodities and some wage rates that they can be used as a measuring stick for the others. Perhaps some of the prices and wage rates are a little too low now and will advance, but the advance would not be large and the decreases awaited are large. Thus tin, copper, zinc, lead and antimony have lately been below their pre-war averages and possibly that is a little too low, but building materials according to the latest report of the Bureau of Labor at Washington are 103 per cent. above their 1913 average and housefurnishing goods are 174 per cent. above. Everybody except those who are trying to sell these is agreed that they are altogether too high. The farmer in particular realizes that, when according to this same report farm products are only 15 per cent. (all figures refer to wholesale prices) above their 1913 average.

As to wages, the building trades are still holding out for an average of more than a dollar an hour, whereas common labor is available in many regions at 30 cents or less.

It is on account of this philosophy that the steel trade holds that the most favorable piece of news as to the prospects of the steel industry for the future that has come out for many weeks past was the announcement made last week by the Railroad Labor Board that a reduction in railroad wages is justified by present conditions. The steel trade would expect to profit by the railroads getting into better financial position, by saving money on payrolls and by having their borrowing power increased at the same time, but the more important influence of the railroad wage announcement, in the minds of steel makers, is the bearing it has upon wage rates generally, for it is expected to encourage wage declines in other directions, particularly in the building trades. In other words, the steel industry feels that the cost of consuming steel is too high and must come down before steel can be bought in large quantities. As to the prices of steel products, the steel mills will make the proper prices when buyers get in position to take hold.

### Prices Steady

The new prices developed for steel products in the fore part of April are being very well maintained. Occasionally there may be a concession on an order much larger than the usual run, but on ordinary busines prices are strictly by the card. There is practically no incentive to cut prices. Costs are high, with a mill running right along at 25 to 35 per cent. of capacity, or operating 50 per cent. in alternate weeks, or with a manufacturer who closes one plant and keeps a second plant operating at 50 or 60 per cent. The only way to decrease cost just now would be by a larger operation, and price cutting would not do that. Costs will come down some when freight rates are reduced, but it will be two or three months before that subject is even taken up. Here and there a slight further reduction in wages is being made by steel mills, but in general the recent reductions are likely to stand for some time, common labor being 33 to 37 cents an hour, with time and a half for hours over eight in a day. The Cambria Steel Company is reported to have reduced to 30 cents lately, without overtime, while the Republic Iron & Steel Company, paying 37 cents, is reported to have cut out the extra payment for overtime.

## Pig Iron Market

THE pig iron market continues dull with a tendency toward further concessios. Reports iindicate that in some sales made at distant points, at least one producer on the lakes has shaded the market freely. A New Jersey cast iron shop purchased about 6,000 tons, this being the only transaction of fair size on the market.

Pittsburgh reports that the past week has been one of the dullest the trade has ever experienced since the recession in buying developed last fall. A sale was made of 2,000 tons of basic iron to a Valley steel maker at $22 Valley furnace, and this business was taken by a merchant producer. Standard Bessemer still is quoted at $24, Valley furnace, but there are only a few carload sales to support this quotation. It is believed that a firm offer of less than $22 for basic iron would get consideration from some merchant producers to-day.

The Chicago market is quiet with only small sales to break the monotony; 200 tons of No. 1 foundry was bought by a Michigan melter at $23.50 Chicago furnace or $23 base for No. 2 material. Most sales from furnace continue to be made on a $23 base, but a few transactions have been closed at $22.50.

A cast iron pipe shop, which recently

took a contract for 6,000 tons of pipe, has purchased pig iron and scrap with which to make the pipe. One company is reported to have taken 2,500 tons of the pig iron at $23.50 furnace base, and another about the same tonnage at about $24 furnace. Definite anouncement as to price has not been made public. Sales for the past week in New York aggregated about 10,000 tons.

The largest sale reported on the Cincinnati market during the week was a sale of 250 tons of malleable iron. Several 100-ton lots were sold, but the majority of the transactions were for carload lots and even these were few. Chicago iron is being quoted in this district and some sales are said to have been made on a $22 furnace basis. There is no activity in basic and the quotation of $24 is only nominal.

Inquiries have been made on the Buffalo market by several buyers, asking prices on quantities of iron for last half of the year delivery. The total inquiry of this kind is slightly less than 3,000 tons, but it marks a departure from the policy which has prevailed amony buyers for many months. Foundries have not been interested in any future deliveries. Shipping on old contracts has not improved. An unusual development has been reported, namely the sale of 250 tons at $30 base by a furnace which has been out of the market by reason of determination to hold to a $30 price.

The local market at Philadelphia continues dull, aside from several fairly large sales of foundry iron to cast pipe manufacturers. Most foundries are calling only for carload lots for prompt shipment. A new Jersey pipe manuacturer about 6,500 tons of No. 2 plain iron, some or all of which was sold at $23.50 f.o.b. furnace. A small tonnage of gray forage was sold last week at $24.50 furnace. One company in this district which has all of its furnaces idle expects to put one in blast soon, probably on malleable iron.

On the Cleveland market there is a slight improvement in the demand for foundry iron in small lots for prompt shipment. Prices are about 50 cents a ton lower with quotations ranging from $23.50 to $24, but some furnaces are making sales at $23 and possibly lower to consumers with whom they have high-priced contracts and who are averaging down their costs by taking part high-priced iron and part present-priced iron. Generally, consumers are buying only for immediate requirements and that policy is bringing about many orders for car lots.

## Scrap Metal

THE scrap metal market at Pittsburgh has shown a stronger tendency in the steel works grades, largely as a result of some fairly sizable purchases by a large independent steel company during the last ten days. This interest recently paid $13.50 for a fair sized lot of heavy melting steel. One dealer now is offering $14 delivered this district, for heavy melting grade, and this is probably as low as any now can be bought.

On the Chicago market the dealers continue to buy material to stock in their yards, in anticipation of a higher market, and in many cases are paying more for this scrap than consumers are now willing to pay. This speculative activity is reflected in a number of advanced quotations.

New York reports a better feeling in the trade which has been reflected in slight price raises in a few items, notably heavy melting steel. Some of the mills from which nothing has been heard for weeks are sending out inquiries and buying small quantities.

Greater inquiry on the Buffalo market indicates to dealers improved furnace operation, and an advance in the price of heavy melting steel may come. A few dealers report a better week than any in recent months. Several sales of No. 1 machinery cast at $18 have been reported,

The tone of the Philadelphia scrap market is stronger, and dealers are not anxious to sell at present quoted prices because of the difficulty in covering on their orders at a profit. An eastern steel plant made purchase of about 1,000 tons last week at $12 to $12.50 delivered, but is now offering $12.

On the whole the scrap market at Cleveland is very dull. Purchases of heavy melting steel by local consumers are reported at $11.50 to $12.50, the higher price being paid for the best quality of scrap. The low prices that are being quoted on machine shop turnings are bringing out very little material. Dealers are offering $8.25 for mixed borings and short turnings, which are slightly lower.

Trading is practicallly at a standstill at San Francisco, in the scrap market. No sales of consequence have been reported recently. Prices are nominal at $12 gross ton delivered at the mill for heavy melting steel, and $30 for cast iron scrap.

### WATCH THE SCRAP HEAP

SAVING $50,000 a year sounds like a large-sized proposition, but, according to a story going the rounds about the superintendent of a large chemical and fertilizer plant in New Jersey, it is very easily accomplished. He claims he has saved his company $150,000 in the past three years, largely because of his ingenuity in applying the oxy-acetylene welding and cutting process. Much of this saving resulted from utilizing materials salvaged out of the scrap pile for the fabrication of equipment that would otherwise have been purchased new.

From the foregoing it would appear that the oxy-acetylene process as commonly practised in production and repair may be profitably extended to embrace a variety of economic operations that in many plants are entirely overlooked.

As in a general way the same class of opportunities may apply to manufacturing plants of other kinds, references to the typical fabrications at the plant noted ought to be of suggestive value. The principal ones are briefly outlined as follows:

In one instance a 4-inch steam pipeline, 300 feet long and carrying 150 pounds pressure, was constructed of second-hand pipe sections joined by butt-welding. This line was put in service three years ago, and has not shown the slightest trace of a leak at any point.

Another instance of the use of scrap material was the fabrication of two oil and water separators from old pipe. These separators were more compact and workmanlike than the manufactured article.

Another example of the use of scrap pipe was the building of a degreasing condenser from this material. The original condenser was built of screwed pipe and fittings and the loss through leakage of gasoline amounted to 18 gallons for every ton of fertilizer degreased. In the improvised welded condenser the loss was reduced to 3½ gallons per ton.

In the conversion of a coal burning power plant to burn oil, $2,160 worth of assorted pipe fittings were saved by welding in small nipples instead of cutting the main line and inserting "tees."

On another job thousands of pipe clamps and bolts were eliminated by welding electric conduit tubing to the web of "I"-beams.

In another case 5 feet "U" bends were made from scrap pipe. These bends, in which the oxy-acetylene flame was used, were not so symmetrical and uniform as the manufactured article, but were much cheaper and proved highly efficient in service.

The oxy-acetylene blowpipe was used also in making stairways and handrails. For treads 6-inch by ⅛-inch steel channels were welded, hollow side up, to steel channel stringers. The treads were filled in with steel borings and cement to make a non-skid surface. The verticals were welded to the sides of the stringer channels, the handrail being laid in a round groove at the top of the verticals, thus completing, after being welded, a staircase that was rigid and permanent. This application eliminated numerous railing fittings and adjustments at various angles of the stairways.

C. Verne Somerville, Superintendent of the Canadian Electrical Steel Company's plant at Montreal, and formerly well known in the electrical industry in Toronto, was accidentally killed while at work on May 21. While in Toronto, Mr Somerville was employed with the Canadian General Electric Company, and British Forgings, Ltd.

DIAMOND
DISC GRINDERS

Good grinding in fast time has made the Diamond popular in a host of shops. The right design and build eliminate vibration and give the operator a perfect surface every time. There is a suitable size and equipment for every surface grinding job you have. Workmanship and material of "Diamond" quality throughout.

May we send you catalogue?

# The Week's Events in Montreal Industry

Charles P. Archibald, who for a number of years has served in the capacity of secretary for the Young Men's Canadian Club of Montreal, was elected to the office of president last week.

* * *

In connection with the construction of the new $6,000,000 Mount Royal Hotel that will shortly be commenced in Montreal, it has been announced that D. H. McDougall, assistant to the manager of the Toronto Power Company, has been appointed secretary-treasurer of the Mount Royal Hotel Company, and that he will have full charge of the construction arrangements.

* * *

The St. Lawrence Welding Works have changed their name to the St. Lawrence Welding and Engineering Works, Limited. This change was deemed necessary owing to the increased activities that the firm is now engaged in. In addition to welding of every description the firm carries on a general repair business, present marine contracts necessitating increased staff and operating hours.

* * *

Absence of freight in sufficient volume on the various railroads has again necessitated the closing down of the railroad repair shops in this district. Both the Point St. Charles shops of the Grand Trunk and the Angus shops of the C.P.R. will be closed from May 20 to June 1. It is expected that next month will see some adjustment in regard to the wages now paid to railroad operators.

* * *

The Dominion Steel Co. announce a change in the hours of work at the Sydney plant. For some time the works have been operating at irregular intervals, employing some 900 men, but this week it was found necessary to close down entirely. When operations are again started in the course of a week or so, it is the intention of the company to confine the working days to two a week.

* * *

W. J. Brown, manufacturers' agent, 117 Youville Square, Montreal, has secured the Eastern Canada agency for Byrne and Griffith, of Birmingham, Eng., manufacturers of steam and hydraulic fittings, and motor car gauges. It might be stated that Payne and Griffith has purchased the sole right to manufacture the Probert and Bridges line of high and low detectors for steam boilers.

* * *

For the first time in its history the U. S. Iron and Steel and Heavy Hardware Association will hold its convention this year in Canada, and the place selected is Montreal. This will be the twelfth annual meeting of the association and will take place on June 7, 8 and 9. The headquarters of the gathering will be at the Windsor Hotel. All of the large steel interests in the States and Canada will be represented. A meeting of the Montreal branch of the Metal and Hardware Association will be held this week to make arrangements for the visiting delegates.

* * *

A glance into future methods of conducting urgent business may be gathered from the fact that Thos. Hall, of the Hall Engineering Works, Montreal took advantage of the newly inaugurated Canadian Aerial Service, operating in conjunction with Bramson Limited, to pay a "flying" visit to Cornwall this week, in connection with some contracts of the firm. A trip that would otherwise consume several hours at the convenience of the railroad, was complete in about one hour.

# A Well Dressed Screw Machine Carries a Geometric in Its Turret

A group of Geometric Die Heads at work for The Greenlaw Manufacturing Co.

For close on to fifteen years The Greenlaw Manufacturing Company have used Geometrics, and their General Foreman says they are the kind of Tools that earn, rather than spend the firm's money. In their shop five Geometric Die Heads and six Geometric Collapsing Taps are at work every day. All their screw thread cutting is done with Geometrics.

*A Mechanical Engineer's comment is:*
*Wherever I go I find Geometric Tools accepted as standard.*

**--- A Geometric Will Solve Your Screw Thread Problem ---**

## THE GEOMETRIC TOOL COMPANY

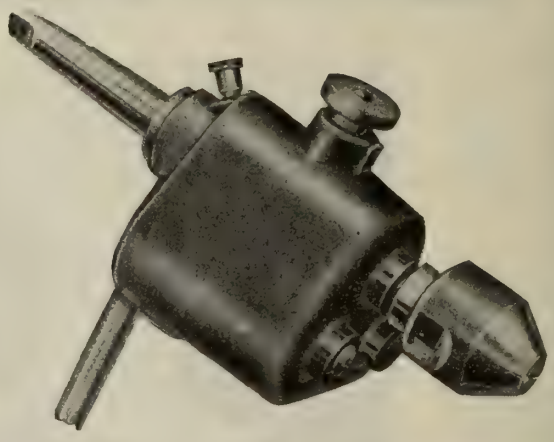
Aikenhead's



# Canada's Leading Tool Supply House

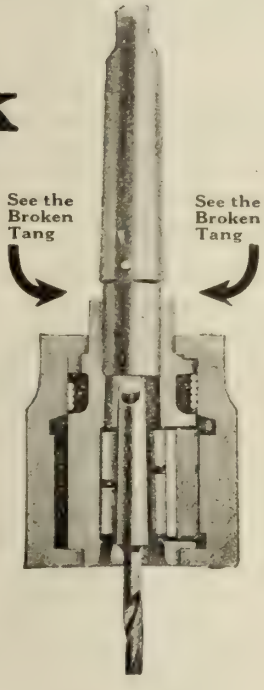
## Wahlstrom's Tapping Attachment

THE Wahlstrom prevents tap breakage by keeping the lands free from chips by means of an oscillating motion which duplicates the simple to-and-fro motion of hand tapping. For tapping in soft materials the oscillating motion can be changed to a continuous revolution.

The Wahlstrom fits any drill press. It is made in two sizes. No. 1 takes taps of all sizes from 5-40 to ½ inch; No. 2 takes taps from ¼ inch to ¾ inch.

# AIKENHEAD

## 17 Temperance Street



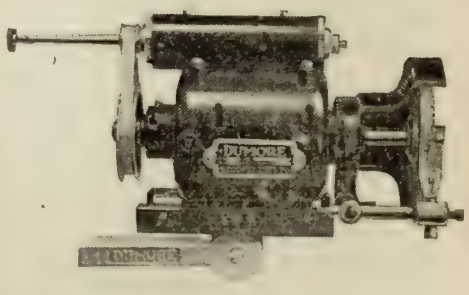
*If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.*

# Everything in Tools

Aikenhead's

## Wahlstrom's Automatic Drill Chuck

WITH a Wahlstrom your operator can drill any number of holes of different diameter, one after the other, simply by grasping the chuck with one hand and replacing the loosened drill with another—and two seconds does it! It is not even necessary to stop the spindle.



This Wahlstrom Automatic self-centres the tool perfectly and its instant-acting jaws close on the entire shank in a grip that becomes firmer as the resistance to the tool increases. The clutch can't slip and the jaws never mark a tool.

Made in two styles. One holds Nos. 1, 2 or 3 Morse Taper Shank Tools—with or without tang. The other is made in three sizes: 15/64 to ½ in.; ⅜ to ¾ in. and 17/32 to 1 in., thus holding all sizes of straight shank tools from 15/64 to 1 in. Booklet upon request.

## LARGE IRON FIND IN NEW ONTARIO ANALYSIS GIVES OVER 55 PER CENT. IRON

ACCORDING to recent report, an important discovery of hematite iron has been made in the Cobalt district. The territory lies within the triangle on the points of which are Cobalt, Porcupine, and Sudbury, and the new deposit lies in the townships of Yarrow and Morel, within 14 miles of the railway at Elk Lake.

### High Grade Ore

The ore is said to be exceedingly high grade, massive hematite, showing in one place over a width of four to five feet, and the owners declare they walked along it for about 150 feet, in which the iron content is approximately 70 per cent. In addition to this massive ore there is a series of four dikes or lenses of quartz and jasper in which the iron content is 55.98 per cent. An analysis from the Morel deposit gave the following results: Iron, 55.98 per cent.; silica, 19.60 per cent.; phosphorus, 0.07 per cent.

Geologists had previously expressed the opinion that nothing more than low-grade iron ore would be found in Northern Ontario, but the ore in sight may be measured in thousands of tons. This information is said to be based on the strength of the opinion of leading mining men and on an analysis made in the Ontario Government ore-testing plant at Cobalt, where some of the ore has been found to contain more than 70 per cent. iron, and with the general analysis showing more than 55 per cent. iron.

The ore occurs in sedimentary rocks, being conglomerate and slate, and its general characteristics are almost identical with the Gogebic iron range, which has made the states of Michigan and Wisconsin world-famous as producers of iron ore. The ore in this new range in Northern Ontario occurs in large lenses, and is traced for close to a mile on the surface.

The discovery was made by Frank Wescott, of Elk Lake, Ontario, and he claims that he knew about the presence of the iron for some years, and has repeatedly shown samples to geologists and told them the district in which he found it. These geologists appear to have disbelieved the story, and refused to accompany the discoverer to his supposed find. It was not until Wescott told his story to B. W. Hartley, a prospector in Cobalt, that he succeeded in receiving attention. Mr. Hartley accompanied Wescott to the scene of the find, and in his own words states that what he saw was "almost unbelievable." He packed out 140 pounds of the ore for testing purposes, and after securing a large acreage of the territory gave out the details.

Hartley and Wescott intend to interest Eastern Canada operators in the development of the deposit, and the general impression is that the discovery may be measured in importance with those of Cobalt and Porcupine.

### Same as Lake Superior

Mining men who are familiar with the Lake Superior regions and the deposits there when shown the ore from the new discovery were heard to remark that it was "Gogebic iron," meaning that it came from the mines on the Gogebic iron range in the Lake Superior region. The new discovery lies in sedimentary formation, conglomerate and slate formation being in evidence, with well-rounded pebbles occurring in the conglomerate. Wescott claims to be familiar with the mining area in Michigan and Wisconsin and declares that the geological structure of the new discovery has many characteristics in common with that big iron field.

Wescott declares that he believes the new deposit in Yarrow and Morel townships may actually be related to the northeasterly continuation of the deposits of the Lake Superior region, which have enabled the United States to lead the world in iron ore production, that country having produced upward of 70,000,000 tons in a single year, the 1919 output amounting to 60,000,000 tons, of which 85 per cent. was taken from the Gogebic, Marquette and Menominee ranges of the Lake Superior region. By way of comparison it may be noted that the iron ore deposits which have been mined to depths of as much as 1,500 to 2,200 feet in the Lake Superior region are of the following composition: Iron, 54.01 per cent.; silica, 6 per cent.; phosphorus, 0.03 per cent.

## Trade Gossip

**Reduction Made.**—A reduction of 15 cents an hour will be effected in the wages of Winnipeg bridge and structural iron workers as a result of the decision of the Joint Council of Industry, presented to officials of the union. The previous wage agreement called for $1.25 an hour. The men have agreed to abide by the ruling.

**Warns Them Away.**—Deploring the influx of men from other cities seeking work, Mayor Wilson, of Windsor, requested newspapers to assist in giving publicity to the scarcity of employment along the border. Scores of men from eastern Canadian cities, the Mayor said, are arriving there looking for work that does not exist.

**New Brokerage Firm.**—A new brokerage firm has been formed in Montreal by Graham Drinkwater under the name of Drinkwater & Co., and the seat of Oswald Bros. has been transferred to Mr. Drinkwater. The new broker is at present connected with Aldred & Co., and previous to that was vice-president of Canadian Fairbanks-Morse Co., Limited.

**Meet In Montreal.**—Probably the vastest aggregation of capital ever represented in Montreal will be gathered there June 7-9 next, when the American Iron and Steel Heavy Hardware Association will hold their twelfth annual convention there at the Windsor Hotel. It is expected that about 250 representatives of the leading iron and steel and hardware corporations of the United States will be present.

**Have Contracts.**—Messrs. Sir W. G. Armstrong, Whitworth & Co., Ltd., of London, England, have recently booked a contract for the construction of docks and the installation of the necessary machinery and plant in Nigeria. We understand the total amount of the contract is £3,500,000 sterling. They have also booked a contract for similar civil engineering work in Portuguese East Africa. The contract sum is approximately £1,500,000 sterling. These contracts will be carried out in their entirety by this English firm, who will manufacture and supply from their own works all requisite machine tools, dock gates, handling machinery, etc.

# GOOD PACKING DOES MUCH TO CUT DOWN LOSS FROM STEALING

THE current journal of the Huddersfield (England) Chamber of Commerce contains an article on pilferage and packing, in which attention is drawn to the systematic thieving in connection with goods in transit, and the question is raised as to what extent packers are responsible. "It is safe to say that if all goods, at all times, were as much at the mercy of thieves as are 'goods in transit' the business world would have to put up its shutters because it could not carry on." While losses are directly due to thieves, it is suggested that it is nevertheless a fact that very often "the sight of means to do ill deeds makes ill deeds done," and one fault of present-day shipping practice is that it affords many opportunities to "make a thief." The object of packing is not merely for protection against damage, but for security against theft, and the important bearing of bad packing not only upon the loss of goods by theft but also upon the settlement of claims for such losses is largely overlooked.

**Some Examples of Faulty Packing**

While there are many examples of faulty packing that help the thief and free the various authorities from responsibility, they are roughly divided, the Journal states, into a few leading types:

One of the most common faults in packing is the use of second-hand cases, which are, of course, comparatively easy to open without detection. The result is that, as officers cannot judge by appearance as to whether goods have been taken out before the cases reached the ship, they are obliged to give a "repacked" receipt, which means that no claim will be paid by the ship for loss or damage by thieves.

Another common fault is the use of new cases with weak lids, protected, it may be, by extra battens around the edge, but the nails of which are driven straight down without clinching, with the result that the top boards drop and the nails "draw."

Cases otherwise satisfactory but not bound with hoop-iron are also frequently used, and are often quite unable to meet the ordinary inside and outside strains. The nails become sprung with a few handlings on train and wharf, and the goods are exposed by their own weight. For these cases, which offer a distinct temptation to the pilferer, the ship will only sign an "insufficiently packed" receipt, which prevents any claim for theft.

Other cases are bound with soft hoop-iron, which actually breaks in handling on and off the freight cars and before the ship is reached. Cases with openings similar to crates in which hooks can easily be inserted, and cases so frail as to be unfit for ordinary handling are other familiar examples of packing which not only throws the loss but most of the blame for pilferage upon the shippers themselves.

The Journal offers several practical suggestions for remedying the evil:

1. Don't use second-hand cases unless they are strong and good and unless they contain articles not likely to attract thieves.

2. See that all cases have good ends and that all nails are properly clinched.

3. Bind all cases with strong hoop-iron at ends and also around middle.

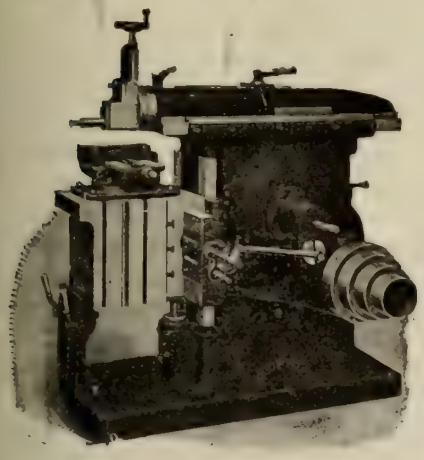
4. Don't use frail cases.

5. Use only hoop-iron that will stand the strain of ordinary rough handling. "Scrap" all old soft hoop-iron.

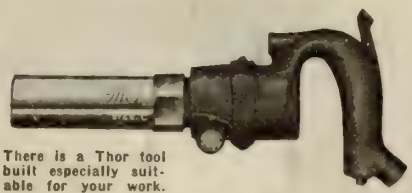
---

Mr. McFadden, of the Diamond State Fibre Company, of Toronto, who has been confined to the hospital at Port Hope several weeks with pleurisy, has fully recovered and is taking up his duties again.

# RAILROAD WAGES CUT ABOUT JULY 1



Work of unskilled railroad workers will be cut July 1, according to a decision made by the United States railroad labor board, which has been conducting hearings in Chicago since the early part of April. The amount of the reduction was not stated in the decision, but will be announced on June 1. Practically every railroad in the country will be affected by the ruling, the total number of unskilled employees approximating 1,000,000 men. The decision came somewhat earlier than was expected, no ruling having been expected for several weeks. At the same time the board announced that on June 6 it would open hearings to receive proposals from the railroads relative to wage decreases for the skilled class of workers, and that the decision reached also would be made effective on July 1. With skilled labor receiving a cut, practically every class of railway workers would be affected, the total number of men employed by the roads being about 2,000,000. The last wage decision of the board was made on July 20, 1920, and increased the pay of all classes of workers about 21 per cent. or $600,000,000 a year.



**Don't stop, you're almost out of the woods.**

# MASSEY-HARRIS CO. STUDIES NEW MARKET

**Shows Example of Good Export Trade Policy By Studying Conditions**

An example of how Canadian firms should enter the export market is provided in the policy of the Massey-Harris Company in extending their field of operations. For a number of years the company has been successfully marketing a combination reaper-binder in Australia and South America. When, however, Spain, Algeria and South Africa were considered, certain changes and improvements on the machine were effected in order to make it more thoroughly suitable to the type of farming and class of people found in these new markets. A number of machines were next shipped over and complete tests and study of the situation instituted. It may safely be said that if mechanical harvesting equipment is saleable at all in these countries, the Massey-Harris Company will secure its fair share of business by these methods.

The case is but a repetition of the advice which men experienced in export problems have always given. The market is available for those firms who will by first-hand investigation find out the local conditions of trade and the particular fancies or needs of the people.

## Trade Gossip

**Want Machines Made.**—An American firm, making a well-known line of vibrators, state they would be pleased to get in touch with any firm in Canada that has the facilities for making their vibrators. The address of this firm can be secured from Canadian Machinery.

**Want Equipment.**—The McIlroy Belting Works, of Kingsville, Ont., want to buy second-hand calendar rolls, 8 by 1[illegible] inches in diameter and 36 by 40 inches long, slow geared. These gears are used for squeezing surplus compound back into the tank after belts are passed through.

**Want Dies Made.**—The Canadian Edison Appliance Co., Ltd., of Stratford, Ont., will have in the vicinity of $30,0[illegible] worth of die work to give out during the year and are anxious to get in touch with outside firms who could handle this sort of work to advantage. They are manufacturers of the Edison, Hotpoint and Hughes lines of electrical goods. D. Fuller, of the above firm, reports that the Hotpoint Iron Week has been a big success. Their plant has been running 24 hours a day for the past month and the chief trouble has been in the securing of raw materials.

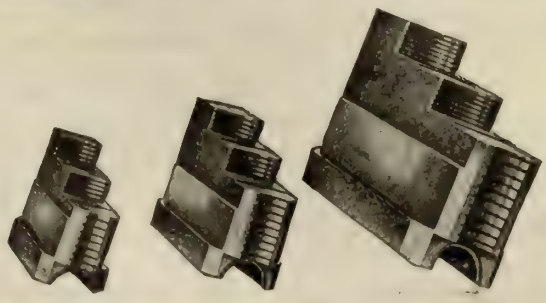
## AUTOMOBILE MARKET

### Studebaker Sales Show 157 Per Cent. Increase For First Four Months

That the buying of motor cars in Canada is on the upward trend is evidenced by the statement of the Studebaker Corporation of Canada, Ltd., who report that their sales for the first four months of this year show an increase of 157 per cent. over the corresponding period last year. They further report that their factories at Walkerville, Ont., have been into full production since the first of April.

## Personals

J. E. Davies, president of the Alberta Foundry and Machine Company, Ltd., Medicine Hat, has been appointed president of the Lethbridge Iron Works Co., Ltd., succeeding C. A. Magrath. Mr. Magrath will continue with the firm as vice-president. V. W. Parrish, who is secretary of the Alberta Foundry and Machine Company, is the new secretary-treasurer of the Lethbridge Iron Works Company.



At the recent meeting of the Electric Club of Toronto, Mr. Frank Kennedy was elected president, succeeding Mr. Geo. D. Perry.

## THE FORD-SMITH MACHINE CO., Limited

**Hamilton, Ontario, Canada**

# CANADIAN HART WHEELS

## *Vitrified — Silicate — Shellac*

**Canadian Hart Vitrified Wheels**—recommended for the majority of grinding jobs. May be used wet or dry; give better all-around satisfaction and have a longer life.

**Canadian Hart Silicate Wheels**—can be made in twenty-four hours and are often substituted when it is inconvenient to wait the required length of time for Vitrified Wheels.

**Canadian Hart Shellac or Elastic Wheels**—indispensable for slotting work where a thin wheel is required, or for work requiring a special finish. Can be operated wet or dry.

**Tell us what you want to grind and we will tell you the wheel to use for the best results.**

## Canadian Hart Products
LIMITED

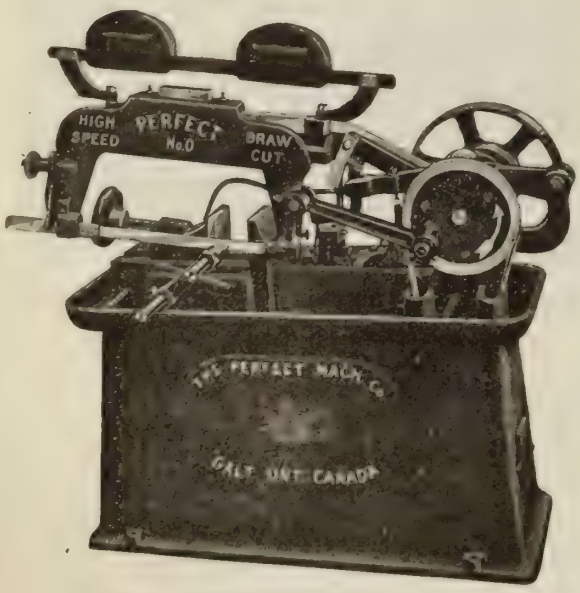
# PERFECT MACHINES

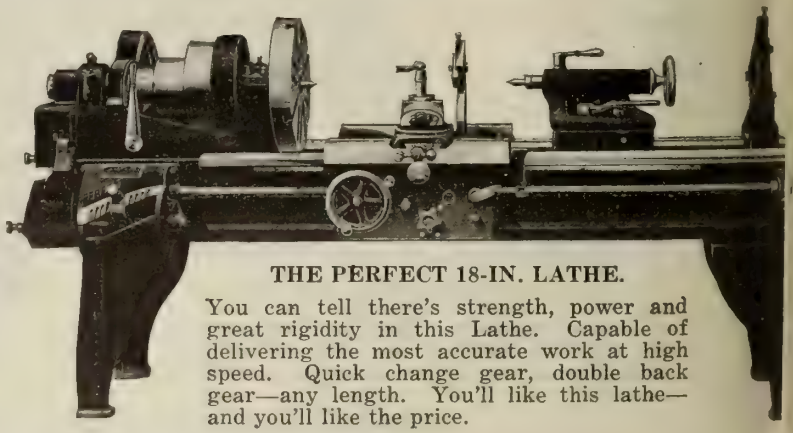
**Perfect 12 in. and 14 in. Screw Cutting Lathe With Gap**

Furnished in 6′ or 8′ lengths. Just the lathe for machine shops, experimental shops, technical schools, garages, etc. Nice convenient design, small consumption of power, and low price.



**Satisfy Your Requirements from this array of Tested Machines**

Every machine we feature here is thoroughly reliable and guaranteed to give satisfaction. We are proud of their "performance" records. Every tool subjected to the most rigid tests before leaving our plant.



**NO. 19 DRILL**

Lots of power here. Handles a drill from 0 to 29/32. Geared 2 to 1, and driven by a 2-in. belt.

**NO. 0 PERFECT HACK SAW**

Look at this sturdy little worker. It's a High Speed tool and **perfectly** built. Capacity 0″ to 6″ or more on request. Speed 120 R.P.M. Weight, 600 lbs.

**THE PERFECT 18-IN. LATHE.**

You can tell there's strength, power and great rigidity in this Lathe. Capable of delivering the most accurate work at high speed. Quick change gear, double back gear—any length. You'll like this lathe—and you'll like the price.

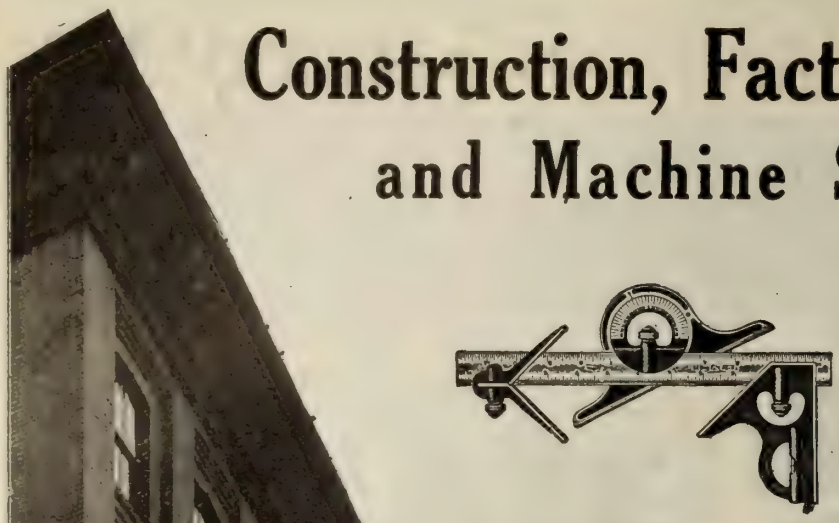
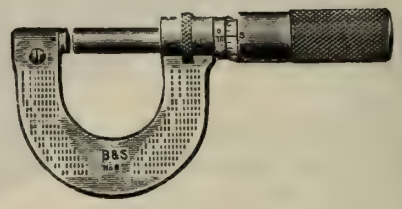
# Do You Read These Advertisements?



Every advertisement in this magazine is worth reading. It is the product of some concern that is using a modern method of making sales, viz., technical paper advertising, in order to present most effectively to you the leading features of its line.

These advertisers are making it easier for you to buy intelligently with the least waste of your time and theirs. They realize that a sales force cannot replace this service at equal cost. They know that advertising is good business, for the manufacturer who does not advertise cannot save the cost of advertising. Consistent advertisers are progressive merchandisers. They are saving your money and their own; and it pays to do business with them.



Don't miss your opportunities. These advertisements are interesting. Many are distinctly instructive, and a glance through them every month will keep you posted on the latest developments for machinery equipment.

# *Let's Be Reasonable*

Does any reader of this page believe that **at this time** a re-adjustment of wages and hours in the printing industry involving an increase in labor costs of 36 per cent. is justified?

"Well," the reader asks, "What **are** present wages and hours?"

Toronto printers now have a minimum wage scale of $35.20 per week for 48 hours. This is an increase of 10 per cent. over the scale called for in the agreement now expiring and was granted voluntarily by employers a year ago.

Their demands now are for a wage of $44 per week for 44 hours.

This is an increase of $8.80 per week for four hours less work.

It means an increase in labor costs of 36 per cent.

Toronto employing printers feel that they cannot grant these demands, and they believe that the general public will support them in their opposition to an increase of from 73c per hour to $1.00 per hour to printers, pressmen, bookbinders, and mailers, **at the present time** and in view of business conditions **as they now exist.**

It is understood that International Union officials at Indianapolis have issued orders to local unions that the 44-hour week must be the basis of all new agreements.

In this order, employing printers believe that these Indianapolis officials are out of line with the need which is apparent in every industry for lower cost of production.

This is not a time for saddling any industry with an additional 36 per cent. labor cost, and publishers and job printers feel that they are justified—in the interest of the public—in resisting this unreasonable demand from Indianapolis.

The issue will be decided between now and June 1st. If the union demands of an increased wage of $8.80 per week for 4 hours' less service are not withdrawn, a strike seems inevitable.

Pressure, therefore, must be brought to bear upon the officials at Indianapolis. They must be shown by members of the local union (many of whom feel that they are being forced to make unreasonable demands) that the Canadian public which buys the product of the printing craft, either in the form of advertising or subscription, does not look with favor upon any ruling which would add so heavily to the cost of that product.

Publishers and job printers in Toronto want to be fair. This is indicated by their action in voluntarily raising wages a year ago.

They must, however, in justice to themselves and the public they serve, resist these impossible demands.

## Let's Be Reasonable

**An expression of opinion of readers of this paper on the Union's proposals, involving an increase of 36% in the labor cost of printed matter, is asked. Will you not write a letter (no for publication) telling him your view of the situation?**

***This statement is published by and has received the endorsation of Toronto publishers who are members of the***

# *Oakite Saves Over $4,000 a Year On One Cleaning Operation*

This Advertisement is one of a series based on actual occurrences.

In a certain plant, small brass parts were washed with soda ash to remove rubber compound. Soda ash left a sediment, so 5 girls had to be employed to scrub the parts with soap to remove the sediment.

This operation was slow, tedious and costly.

An Oakite representative was given an opportunity to investigate cleaning conditions in this plant. The use of 30 lbs. of Oakite every week to replace 444 lbs. of soda ash was recommended and Oakite was adopted.

The parts now come from the tank absolutely clean. No sediment. No scrubbing.

Oakite has saved this plant $83.52 weekly on one cleaning operation—or more than $4,000 a year.

We have a representative in your territory. May we ask him to call at your plant and have him go over your cleaning requirements with you? This will take but a few minutes of your time, and you can find out just what it would involve to run a competitive test on your work. He can perhaps indicate just what results you can expect and offer suggestions as to methods and materials best suited to your work.

Now is the time to cut expenses. A request from you for an Oakite service man to call to look over your cleaning problem places you under no expense or obligation whatever. Write to-day.

**Resident Canadian Representatives: Mr. C. P. Murphy, Toronto, and Mr. C. Burgin, Montreal**

# BRADLEY HAMMERS

*Upright Helve Hammer*

## When the Work is Severe and Continuous

The Bradley Upright Helve Hammer is of that type in which the head or ram is operated vertically in guides or ways.

As the dies in this style of hammer are always parallel regardless of the opening between them, it is most desirable for general jobbing of a severe nature, where frequent variation in the size of stock occurs, and where forgings are made from flat stock that must be edged up.

*"Forge Ahead with a Bradley Hammer"*

The Bradley Upright Helve Hammer we recommend where the work is exceptionally severe and continuous. For work of a lighter nature of the same style the Bradley Upright Strap Hammer is our choice.

Bradley Hammers contain more material than others. The Anvil Blocks are much heavier in proportion to weight of head. Their design and the workmanship put upon them are of the highest order. They are Cushioned Hammers in the very best sense of the word. These are some of the features that justify us in guaranteeing them to do a quarter more work with less power and fewer repairs than any other belt Hammer in the world.

Franklin Die-Castings Used in Vending Machines

# *Speeding Up Distribution*

The strenuous life of to-day has practically crowded out leisure even at meals. "Automats," which now supplant old time taverns, save the business man valuable time, while smaller vending machines for distributing confections and matches add to his comforts.

This need for speedy distribution has been aided by the application of Die-Castings to vending machines.

In 1892 we originated the Die-Casting Process, and for nearly thirty years we have been reducing the cost and simplifying the output in many fields of industry. The addition of the standard No. 12 Aluminum to the Tin, Lead and Zinc base alloys already in use has enabled us to meet a still wider range of individual needs.

# Overhaul Your Furnaces Now

IT WAS neither feasible nor politic to shut down your furnaces when prices were at the top and demand was greater than supply. Everything had to be sacrificed to production! Cost was a secondary consideration.

But those days have gone and now we are faced with the necessity of getting down to bed-rock in the matter of production costs, or going to the wall.

Lloyd George says Germany must pay her debts to the Allies in goods—that means low-priced imports, and if the home market is to be kept for Canadian manufacturers, they must set their house in order and look carefully after their manufacturing costs.

"Oilgas" furnaces have proved to be a most important factor in helping many Canadian manufacturers to cut their heat treatment costs in two. What they have done for others they can and will do for you.

Our Engineers are available for conference at your plant any time at your convenience, without any obligation on your part.

Oilgas furnaces are different. They are made in Canada with Canadian capital.

Every furnace bought abroad adds to the discount at which Canadian funds are held. Patronize home industries.

# HIGH SPEED
## RIVETING HAMMERS

**Speeds Production for the Robbins & Myers Company**

**The Hammer with the Human Stroke**

AN immediate production increase was the result of installing a High Speed Riveting Hammer in the plant of the Robbins & Myers Co., Brantford, Ont.

The work caught by our camera man is Riveting Formed Fan Punching to hub. It demands neatness and speed—to conform to the high standards of this plant.

It takes just half a minute for this work — no comparison with the laborious method of hand sledging. Send us samples or blue-prints and we will quote production figures.

Besides often as much as quadrupling production, High Speed Hammers also better the quality. Hand work cannot approach them for uniformity and fine finish.

YOUR DEALER WILL FURNISH THEM

# THE FOUNDRY GALT, ONT.

TRADE K—T MARK

# Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

## If you need some new Patterns

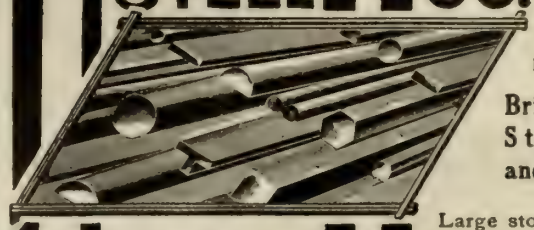
send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. **Ask us.**

***We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.***

*If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.*

GEARS AND PINIONS



Any Kind of Gear

We make a specialty of rawhide and silent Micarta Pinions for noiseless drives.

"Hurry Orders and Break-Down Jobs" receive special attention. Try a catalogue—it's interesting, and contains a lot of gear data.

## DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

MACHINE SCREWS

## When you send us one order we expect more!

UNLIKE some manufacturers we do not try to make a large profit on one order by charging an exorbitant price for the quality put into the products.

We believe that the repeat orders which result from selling high-grade products at moderate prices are more profitable to a firm in the end.

To convince yourself that machine and special screws, as we supply them, are far better value than any you have had in the past, write us for samples.

*Manufacturers of standard and special machine screws, rivets, threaded wires and specialties in head work. Large quantities carried in stock for Quick Delivery.*

## THE TORRINGTON COMPANY, LIMITED

UPPER BEDFORD, QUE.

# BANFIELD

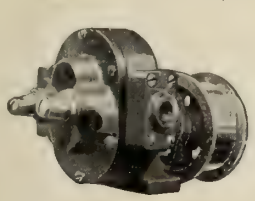
DURING recent years this company was compelled to decline much desirable business and many connections that would have been highly appreciated, because enquiries could not be considered without prejudice to the important government work entrusted to us.

Present conditions suggest an opportunity for you to establish connections with a concern whose manufacturing facilities are not excelled in this country, and whose record on the important matter of service makes such a connection a real asset.

We are equipped to handle stampings in all metals, gauges and finishes.

You blueprint or sample will bring you our estimate.

**W. H. Banfield & Sons, Limited**



TORONTO

REG. TRADE MARK

# TRAHERN

## TRAHERN PUMPS SAVE TOOLS

By delivering to your machine tools a steady, forceful supply of free-from-grit coolant, Trahern Circulating Pumps add life to cutting tools. Trahern Rotary Geared Pumps have every essential—low speed, large capacity and long life. They pump water, oil or compound and will operate against 100 lbs. pressure, reverse automatically with machine and supply of coolant may be shut off at discharge without stopping pump. Typical installation shown in centre picture.

# STAYBOLT TAPS

## The Better the Man, the More He Appreciates Them—

Not only good when new, but heat treated and seasoned to maintain this goodness. Can be ground on face of cutting edge without affecting their size. That's why you'll find Pratt and Whitney Stay Bolt Taps on the job long after cheaper, "just as good" tools are buried in the scrap pile.

Threads accurately and cleanly cut, with the least expenditure of time and effort, are other reasons why these better Taps are favorites in the shop.

If you've used them before, you know just how good they are. If you haven't, send us your first order—we know you'll be back for more. They're carried in stock in our sales rooms in all large cities.

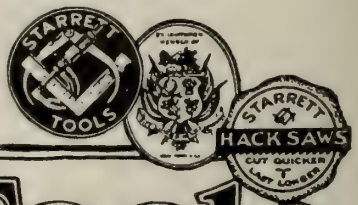
# Accuracy First—

"Remember that accuracy is the first requirement of a good machinist. Speed comes after.

"Starrett Tools are absolutely accurate. You can depend on 'em.

"In the long run, that means more than getting jobs done right—it means saved time and saved material. All of which helps save your job when the tool-borrowing, time-wasting, botch workers are being weeded out of the shop.

"Overhaul your Starrett Tool kit first chance you get. Make it complete. Keep watch for the new Starrett Tools and get 'em. The more Starrett Tools you have, the better you are fixed to handle any job you get.



"When you go home tonight, it would be a good idea for you to drop into the hardware store and look over the Starrett line.

"Get posted on tools you need. Write for the Starrett Catalog No. 22 "3."

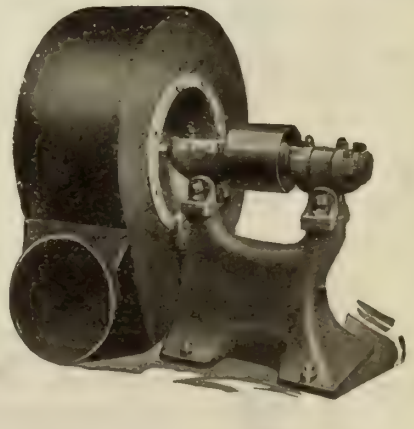
# No. 4 Alfred Herbert Capstan Lathe

**Swing 13". Bar Capacity 1⅝" x 10"**

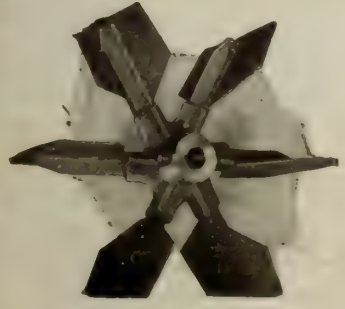
Our No. 4 Capstan LATHE, commonly called by machine tool users a universal turret lathe, on account of its wonderful versatility, presents a machine admirably adapted for small chuck or bar work within its capacity and is largely used on such work as wing pump bodies, carburetor parts, and general brass work, etc., etc.

*We will be very glad to submit production estimates on receipt of your blue prints. This service is of course rendered without any obligation on your part.*



## Alfred Herbert Limited

**1-3 Jarvis Street, Toronto**



*We carry in TORONTO a very comprehensive stock selection of turret lathe tools, such as box tools, roller steady turning tools, etc., etc., and solicit the favor of your esteemed enquiries.*

# "CANADIAN" MILL EXHAUSTERS

## *Handle Any Material*

The Canadian Standard Mill Exhausters will handle any kind of material efficiently—sawdust, shavings, cotton lint, or stringy material, gases, fumes, smoke, etc.

They are adjustable to any angle of discharge instantly —have universal type of wheel and carefully constructed, self-aligning oil-ring bearings.

Catalog 410-77—gives technical data and prices. Write for a copy.

## Canadian Blower & Forge Co. Ltd.

# LA SALLE

## Has an Advantage Over Other Grinders

There is some outstanding feature of all La Salle Grinding Machines that lends it exceptional productive ability.
The American Drill Grinder is especially adaptable for grinding twist, flat and three-lipped drills, because it has automatic lip rest and caliper jaw device, which assures proper clearance on all sizes of drills automatically. Send for descriptive matter covering our entire line of grinding machinery.

American Drill Grinder
For Wet or Dry Drill Grinding 1/8" to 2¼". Also 1/8" to 3½" dia.

# Cleco Pressure-Seated Air Valves

## Bowes Air Hose Couplings—Cleco Never Slip Hose Clamps and Cleco Grooved Hose Nipples and Hose Clamp Tool

**STYLE O.F.** is an Outside Thread Female Pipe End. made in sizes ¾-inch to 1½-inch.

**STYLE I.F.** is an Inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.

**STYLE H.F.** is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

**STYLE H.M.** is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼ inch to 1½-inch.

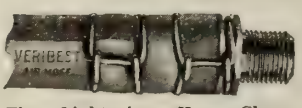
**STYLE O.M.** is an Inside Thread Male Pipe End. Made in sizes ¼-inch to 1½-inch.

**STYLE I.M.** is an Inside Thread Male Pipe End. Made in sizes ¾-inch to 1½-inch.

The Male and Female Ends of Bowes Couplings interchange in sizes ¼-inch to ¾-inch. Sizes 1-inch and 1¼-inch interchange. The 1½-inch ends interchange only with themselves.

### BOWES COUPLINGS

Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-inch.



### CLECO VALVES

**Style P.O.** **Style M.O.** **Style A.**

Style P.O.—Made in sizes ¼ in., ¾ in., ½ in., ¾ in., 1 in., 1¼ in., 1½ in., 1¾ in., and 2 in. Pipe Outlets. Inlets are one pipe size larger.
Style A—30° Angle Valves, are made in sizes ½ in., and ¾ in.
Style M.O. Valve—Has 1 in. Inlet and Bowes Coupling Outlet. Connects with Bowes sizes ¼ in. to ¾ in.

### CLECO GROOVED HOSE NIPPLES

Grooved Nipples when attached to the Hose with Wire Clamps as illustrated cannot "blow out." Wire clamp tool shown below applies the wires to hose.

**The Lightening Hose Clamp Tool** illustrated applies wire clamps at a cost of 1½ cents each.

**In stock:** Riveting and Chipping Hammers, Air Drills, Emery Grinders, Sand Rammers, etc.

Use Annealed Wire No. 14

**IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and Cleco Valves, which will stop costly leaks.**

**Bulletins Nos. 43, 44, 46 and 47 mailed on request.**

**THE MODEL HOSE LINE** illustrated shows correct styles of couplings and valve to use and proper way to attach the Cleco Never Slip Hose Clamps to Bowes Couplings. No "blow-offs" can occur when "Cleco" Clamps are used.

# The "Lehmann" Improved Selective Head Lathes
(Patents Pending)

SIZES—14" to 24" SWING

On account of its simplicity of construction, great driving power and rigidity, ample range of speeds, moderate tooth travel of its gears, compact and shapely appearance, the "LEHMANN" Selective Head Engine Lathe stands to-day in a class *ahead* and *alone*. Some of the features of construction are:

Sixteen Spindle Speeds in correct geometrical progression obtained with the use of only ten gears.

Improved Friction Clutches (Patents Pending) running in oil, requiring no adjustment and giving forward and reverse control to spindle.

Heat-treated or Hardened Steel gears.

All Shafts, except spindle, running on ball bearings.

Spindle of alloy steel, hardened and ground at the bearings and running in phosphor bronze boxes.

Head Casting forms oil-tight case enclosing all running parts.

In addition these lathes embody all features such as the patent quick change mechanism, the tailstock spindle locking device, the rod and screw shift, etc., forming part of the "LEHMANN" Cone Head Lathes which have acquired an enviable reputation for accuracy and production.

*Let us describe more fully this Exceptional Lathe and its Distinctive Advantages*

Chouteau Avenue at Grand

*If interested tear out this page and place with letters to be answered.*

# THE JOHNSON FRICTION CLUTCH

## The Case Against the Countershaft

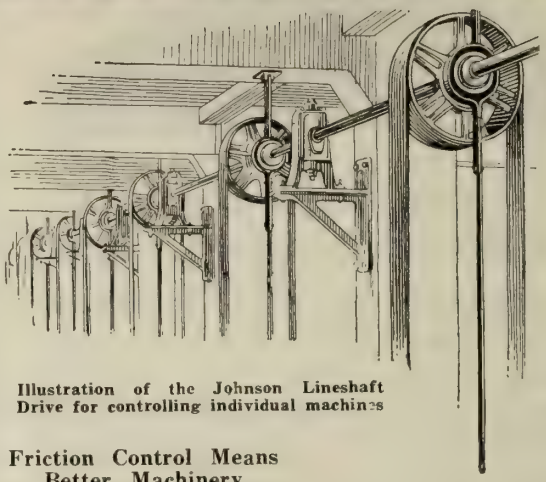
The old familiar countershaft drive, through cross belts and tight and loose pulleys, stands accused of the following offences against efficiency:

1. Involves needless equipment.
2. Costs too much to set up.
3. Prevents economical and systematic use of space.
4. Operates sluggishly.
5. Multiplies belt troubles and the resultant cost of upkeep.

Modern practice has discarded the antiquated countershaft for the simplicity and efficiency of the clutch drive direct from lineshaft.

**Adopt the Johnson Lineshaft Drive**

The economical, efficient and durable method of power transmission through friction control.



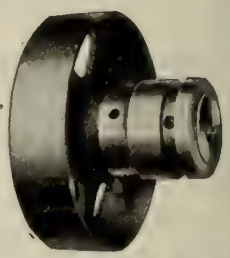


Illustration of the Johnson Lineshaft Drive for controlling individual machines

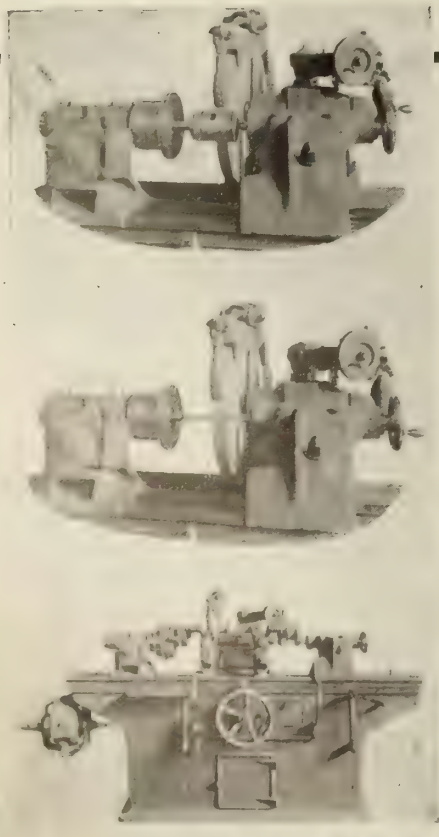
**Friction Control Means Better Machinery**



Whether it is applied overhead or in the machine itself.

Write for our Booklet "Clutches as Applied to Machine Building" and our Yellow Catalog.

## Sufficient Weight and Power to Handle Modern Production

Though small in size, the "Economy" Double Back Geared, Quick Change Engine Lathe is strong and powerful. Its extreme accuracy makes it particularly adapted to the tool room of the modern manufacturing plant. Made in 14 in., 18 in. and 22 in. swing.

**Write for complete information of this small, heavy duty lathe, without delay.**

**Rockford Lathe and Drill Co.**
**Rockford, Illinois, U.S.A.**

# RAPID
## SAWING MACHINES

**Fast Cutting Production Tools that eliminate the waste in cutting.**

Note the powerful design. Absolute strength and rigidity.

**Rapid cutting is obtained without the use of heavy weights.**

FEW Sawing Machines can compare with this "Rapid" for fast cutting ability, length of life, low up-keep and cutting-economy. On most work it is a decided advantage over circular or hand saws.

The simple, rigid construction and minimum of working parts is an insurance of cheaper and better work. 3,000 of these machines giving satisfaction.

**Made in various sizes to take bars from 6" up to 26 diameter.**

**Write for particulars to**

**WILLIAMS & WILSON LTD.**
84 INSPECTOR ST., MONTREAL

## Buried in the Work and Broke!

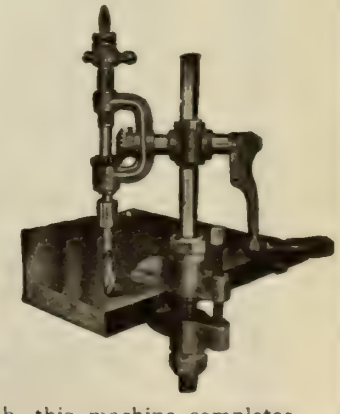
Next time a tap breaks below the surface of a large casting, don't let some make-shift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

## Walton it Out in a Jiffy

And save the casting.

Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

**Sixty-day trial offer** proves the Walton Extractor pays for itself.



**Write.**

**The Walton Co.**
**Hartford, Conn.**

## Jardine Universal Ratchet Drill

Time is expensive when a machine is standing idle, waiting for repairs.

On the average repair job, this machine completes the drilling in less than the time required to set an ordinary ratchet to begin.

**Weight, 40 lbs. Price, $26.50 net.**
**Sold by all Machinery and Supply Houses.**

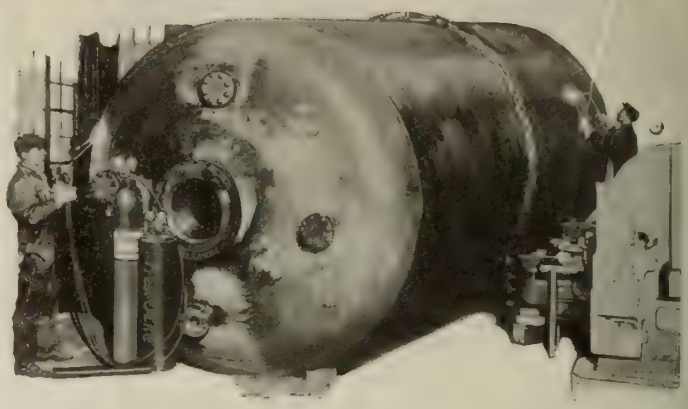
# Leak Insurance

The Welded Tank answers ideally the demand of the industrial engineer for tanks which must be tight, strong and permanently leak-proof.



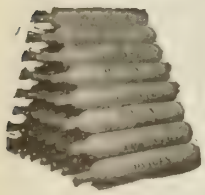
The oxy-acetylene process has made such tanks possible and

Prest-O-Lite

DISSOLVED ACETYLENE

because of its high quality and extreme portability has increased the usefulness of the welding and cutting torches a thousand fold.

Especially is this true wherever large, cumbersome sections are to be welded—Prest-O-Lite can readily be carried anywhere—it goes to the job.



Tank makers are assured of the highest quality of gas and a constant and unlimited supply by using Prest-O-Lite.

A chain of plants and warehouses is kept busy meeting the demand for this most useful of gases.

# Dominion Oxygen—

## *The Route Finder.*

AN order placed with the Dominion Oxygen Company Limited, means an order filled on time and delivered on time.

When the ordinary routes of transportation are blocked—when strikes and storms and tie-ups conspire to defeat prompt deliveries—there is always a way open to Dominion Oxygen. Whether it reaches the consumer by trolley, by water or by motor truck—whatever the routing and whatever the added expense — the promises of the Dominion Oxygen Company Limited are fulfilled.

We call your attention—pridefully—to such Service as part and parcel of our system, where all energies are bent to the end of a perfected product backed by a policy of deliveries that is equal to any emergency.

Our expansion program for 1921 has now reached the point where six centrally located distributing stations at Toronto, Hamilton, Montreal, Welland, Merritton and Windsor are in full operation. Thus we are enabled to fill your order with oxygen of the highest purity on the day it is received and to make deliveries of any quantity, anywhere and whenever needed.

## The Application of Disc Grinding—Miscellaneous Work Performed—Grinding Gear Covers—Manifolds—Cast Iron Pipe Flanges—Drop-Forged Parts—Cast Iron Tanks and Car Brasses

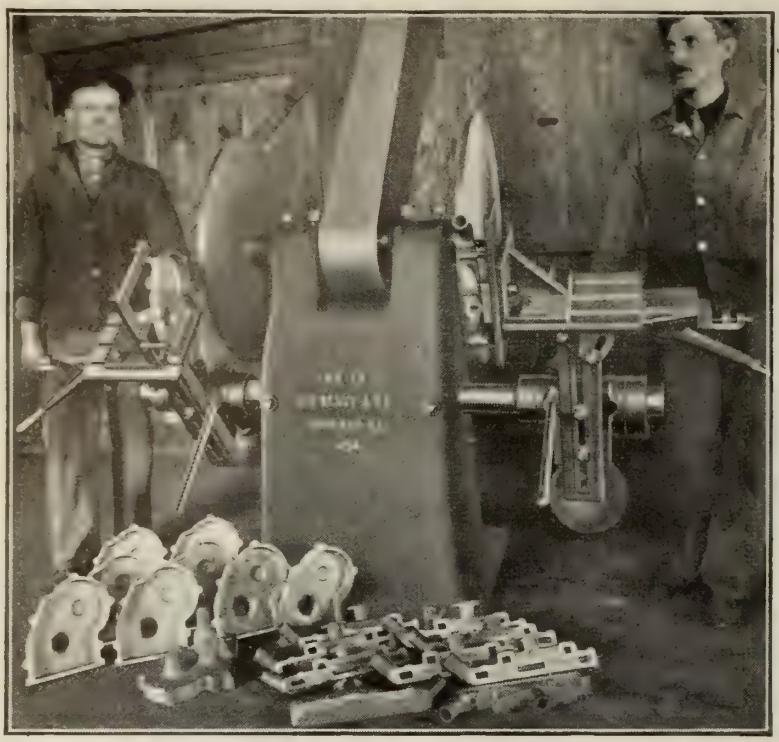
By J. H. MOORE

THE exact date of the origin of "Disc Grinding" is something over which considerable discussion ight be started. In fact it is frankly mitted by some that they do not know 10 originated the idea, although it is nown that abrasive papers have been anufactured since about 1840, and it quite certain that the process of disc inding has been used for more than lf a century.

When the disc grinder was first ought out, about twenty years ago, rcles were cut from commercial emery th, and at that time answered the rpose fairly well on light finish grind-, although they were not suitable for moving much stock. Since that time velopment, both in the machines, and the abrasive circles used, has been ry rapid, until at the present time disc inding has reached the stage where can be termed an essential manufac-ring operation, not merely a finishing ocess.

Various features have been added to e grinders generally, but perhaps the ief improvement of all is the design the modern work table. From a common flat resting slab, we now have tables that have all modern improvements, such as slots, lever feed, micrometer adjustment, etc. The work can now be held in any desired position and forced against the abrading disc at whatever pressure is desired. Of course there are numerous other improvements. For example, the spindles on disc grinders are now of the latest design and are able to withstand heavy duty. In other words the design of the machines has progressed at equal rate with its new uses. Even the disc wheels have received careful attention, such wheels being usually made of wrought steel, specially treated to eliminate strains in the metal. They are carefully machined, are practically flat and of uniform thickness to within .001 inch and can run at much higher speeds than they formerly could.

The types of machines have also branched out, until we now have the single spindle, the vertical spindle, the double spindle and the patternmaker's style of grinder. All have their own particular field of usefulness, and later on we shall show examples of work completed on the various types. To describe in detail the field for such machines would occupy considerable space, without accomplishing anything in particular, so sufficient to say that to our knowledge over 250 lines of manufacture are using the disc grinding process to speed up their production.

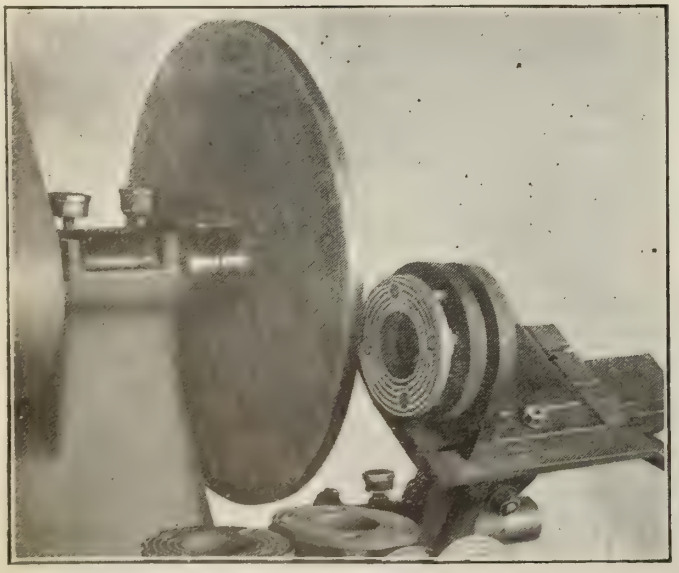


### The Application

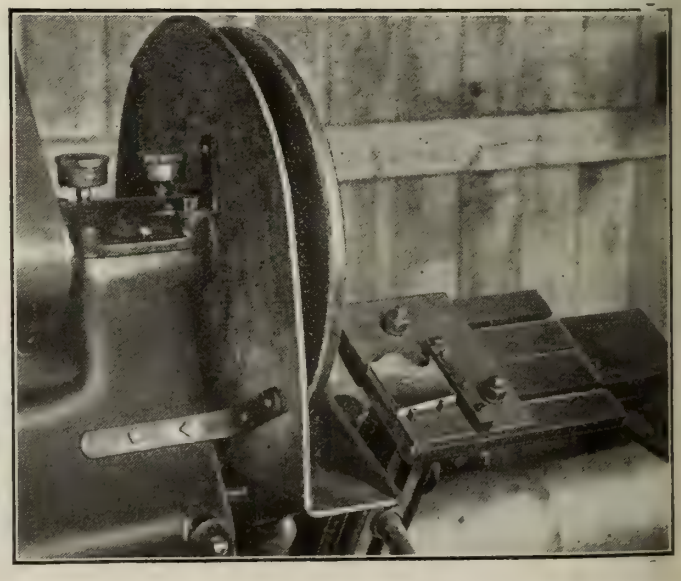
The success of any grinder depends largely on its application. A manufacturer can easily be disappointed in such a machine, if he does not give it a proper chance to produce. Let him treat it as a machine tool, for such it is. One would not think of placing a first-class lathe in some dark, out of the way corner, yet quite often in passing through a plant you will see a disc grinder shoved away into some corner, where it will never get a chance to accomplish its best work. In spite of these conditions disc grinders work satisfactorily, so that given better treatment they can produce still further work.

Another point to watch is the use of jigs and fixtures. Wherever quantities of similar prices are being turned out it pays to design some simple holding fix-

A MISCELLANEOUS COLLECTION OF PARTS PRODUCED BY DISC GRINDING. NOTE THE RECESSING IN ALL OF THESE CASTINGS.



The photograph shows a 14-30"-L Besly grinder at work on gear covers and manifolds for automobile engines. This clearly illustrates the simplicity of work holders which can be used with such grinders. The work shown was ground from the rough casting at the rate of 60 surfaces per hour per operator. As the machine accommodates two operators, the above production may be doubled.



ture for the part, as in this way handling time can be reduced to a minimum. The time spent in the making of such fixtures will be soon wiped out by the large cost reductions that will ensue.

The design of the pieces to be ground is without doubt most important. It is often possible to redesign a part in such a manner that the operation time can be considerably reduced. The chief aim should be to present to the abrading disc as small an area to be ground as possible. Many parts formerly manufactured on other types of machine tools have been redesigned in such a way that by disc grinding 50 per cent. to 90 per cent .operation time has been saved. The selecting of proper abrasive circles is equally important, and when in doubt it is good policy to put your problem directly up to the maker of the machine or discs.

In selecting work for the disc grinder these points should be kept in mind: The amount of stock to be removed, the distribution of the ground surface, the total area of the ground surface and the thickness of adjacent stock for absorbing the heat from grinding, and for resisting distortion. By exercising care in the design of the piece, production will soar, and the operation cost drop accordingly.

The allowance for finish on parts to be disc ground is very much less than in such operations as planing, milling, shaping, etc., and designers who understand disc grinding practice generally call for disc grinder finish on their drawings. The patternmaker on seeing such a notation leaves very little finish on the pattern. In fact a molder will often "rap" a pattern enough to leave sufficient stock for grinding.

The photograph to the left shows a 14-30"-O Besly grinder surfacing from the rough cast iron pipe flanges, 10" outside diameter and smaller. Time, 100 to 300 surfaces per hour. Face of casting is corrugated to facilitate grinding. Corrugations also make a better holding face for gasket. The work holder is of the floating type with ball and socket joint and embodies other novel features which aid in the quick handling of the work. The use of this device allows the ground surface to clean up with the removal of the minimum amount of stock and practically doubles the production as compared with the use of an ordinary rigid angle plate.

The photograph to the right illustrates a Besly disc grinder facing the sides and edges of drop forged parts, used in the construction of metal shear. An inexpensive work holder is used, this being clearly seen in the photo. Note that locating pins are used and are so stationed that the edges of the parts are ground to the required angle.

### Amount of Stock Removed

The cost of grinding is usually direct- proportional to the amount of stock moved, so, as stated previously, it is esirable that the minimum finish be left the surfaces to be disc ground. Chas. . Besly & Co., Chicago, whose machines e show in operation throughout this rticle, find that in practice the removal f .005 inch to .050 inch of stock is sually enough to clean up a surface, lthough they have seen as much as ¼ ch ground off some brass and cast iron rfaces with profit. Generally speak- g, however, here is the amount they llow in actual practice on various work.

Drop forged wrenches: .008 inch to 015 inch.

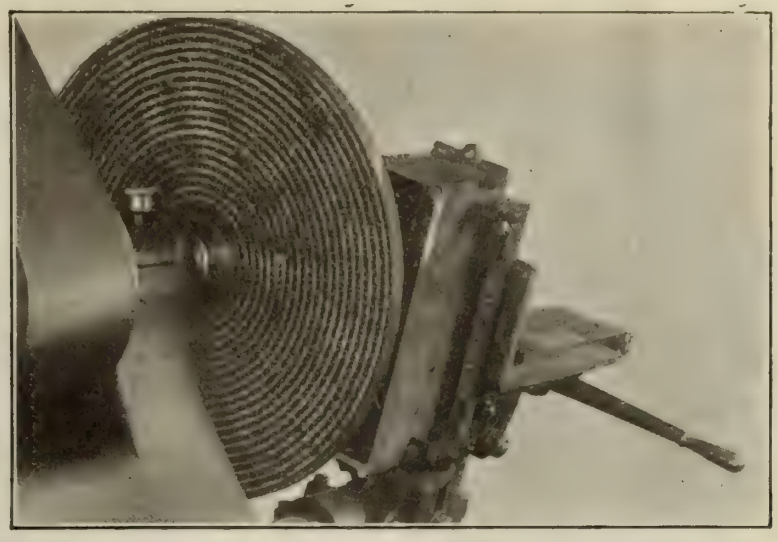
Brass hexagon nuts up to 2-inch iameter: .015 inch. On larger sizes up .030 inch.

Steel punchings: .005 inch to .015 ch.

Cast iron machine parts: 1/32 inch 1-16 inch.

Cast brass machine parts: 1/64 inch 3-32 inch.

These amounts may vary one way or he other and much depends on the na- ure of the material, the speed of the brasive and the distribution of the round surface.



### Points to Remember

Cast metal is more easily ground than olled, or wrought metal, and soft metal easier ground than hard metal. Where on castings are small and thin, the on is often denser and harder to grind an in larger and thicker castings. cale on castings and forgings is harder n circles than clean metal, and where he scale is excessive, it is good policy remove it before disc grinding. The cale can be broken up by the use of itrified grinding wheels, either the ordi- ary type running on solid emery wheel tands, or ring wheels held in special ing wheel chucks running at one end f the disc grinder spindle. In other ases the scale is broken up by tumbling, and-blasting or pickling. Where a orging or hot rolled material is ex- essively scaled, the best method for emoving it is by pickling.

### Speed of Abrasive

The speed at which the abrasive ravels is important, and on the softer naterials a higher speed is required than n the harder metals. As the abrasive t different points from the center to eriphery of the disc wheel runs at dif- erent speeds, it would seem that the peed of the wheel was not of great mportance, but actual practice has hown that the average speed of the brasive is of the utmost importance.

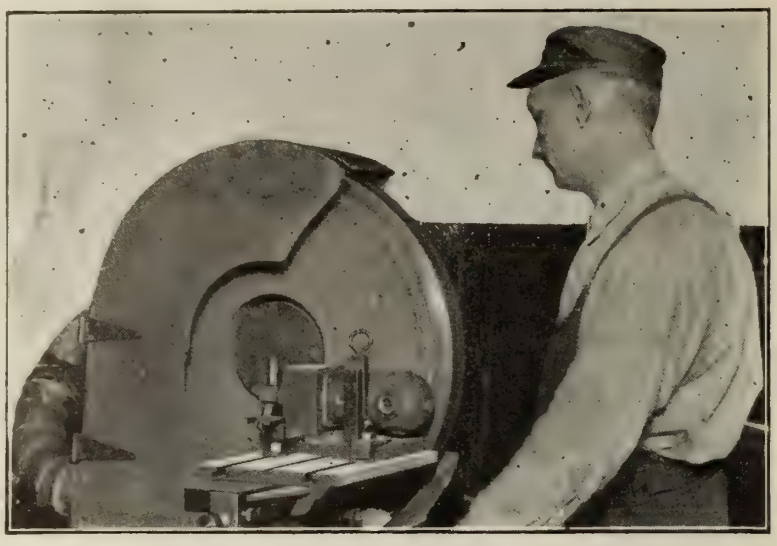
Where you are in doubt it is good pol- y to consult the maker of the disc, tell im all details of the work you are pro- ucing, in this way getting the benefit f his experimental and practical experi- nce. For example, it is generally known that too high an abrasive speed on the hard metals tends to glaze and dull the circles; that too slow a speed on the softer metals tends to fill and clog the circles; while too high a speed on wood tends to burn the work. In spite of this knowledge being existent, many plants continue to waste abrasive discs through not watching these points.

Here we see the grinding off the tops and feet of rectangular cast iron tanks, 5 inches deep and varying in length from 9 in. to 20. in. On this work it is not necessary to grind to size or exactly parallel. The surfaces must be straight and flat and the manufacturing cost low.

An ordinary angle plate is bolted to the geared lever feed table. 30 in. grinding discs are used. The work is forced against the grinding disc by a single ball point, projecting from the face of the angle plate and bearing on the centre of the work, so that the work is free to "float" against the grinding disc and clean up with the removal of the minimum amount of stock.

The work is supported and approximately centred on the ball point by a simple frame bent up from 1 in. square rough bar steel mounted on the face of the angle plate. This frame is drilled to carry adjustable stops for approximately centring the work on the ball point. By raising or lowering the frame on angle plate and changing the position of the stops, the one frame is used for grinding many different sizes of tank castings, varying in width, depth and length. The position of the ball point on the face of the angle plate is not changed.

These long castings are ground in a vertical position. This is desirable on such long work, as it keeps the circle in better shape, the work is handled more quickly and it grinds nearer flat and straight than if supported in a horizontal position. The tops of castings 20 in. long by 5 in. wide are finished from the rough by unskilled labor at the rate of 50 per hour, or eight times faster than the previous milling time.



The same fixture is used in grinding off the feet on these castings; the ball point in that case being on the end of a stud projecting far enough from the face of the angle plate to reach the inside of the bottom of the tanks and allow the work to float against the grinding disc.

### Distribution of Surface

Disc grinding should be completed dry. In other words water should never be used for carrying away the heat generated in grinding, because water will destroy the circles. Heat is, of course, caused by friction in grinding, while friction is caused in turn by the abrasive grains rubbing on the work, and the ground particles rolling between the circle and the work.

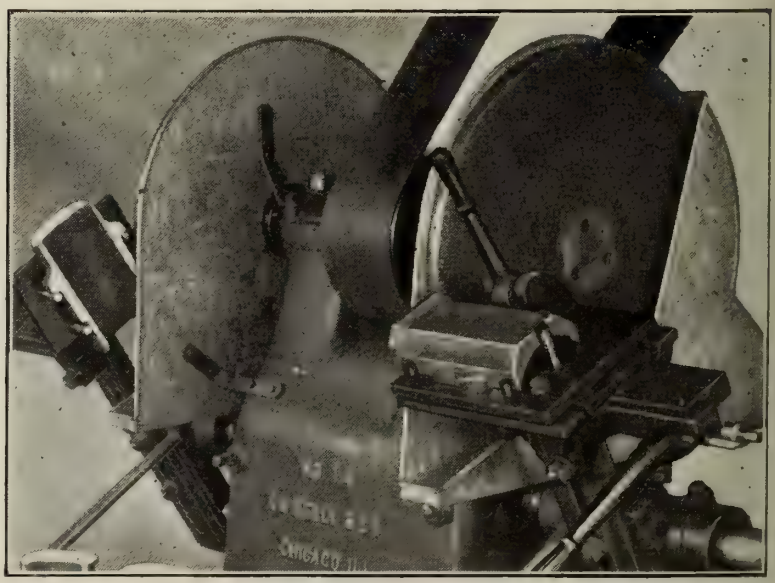
In disc grinding, the entire face to be surfaced is usually in contact with the surface, so that hundreds or thousands of cutting points are at work simultaneously. These cutting points are working at a very high speed, and the more cutting points at work, the more friction and heat. Thus a sharp, free cutting circle creates less friction than a dull or glazed one. Where feeding pressure is insufficient, the cutting points rub and burnish the work, creating excessive friction and consequent heat.

Most of the heat generated in disc grinding is from friction caused by grindings (or ground particles) rolling between the circle and the work. The greater distance these grindings are carried between the circle and the work before being discharged, the greater the friction and heat generated. Excessive travel of grindings is the principal cause of heat, therefore the distance travelled by these grindings before being discharged from circle is one of the most important considerations. It is at this point that the benefit of properly designed work shows up, for where a surface is broken up by indentations, into which the grindings discharge, less heat is generated because the travel of grindings is reduced.

In the production department at the Evinrude Motor Company's shops in Milwaukee, they keep three disc grinders busy all the time, surfacing a variety of bronze, brass and cast iron parts, many of which were previously milled. The operation shown is surfacing carburetor flanges on cast iron cylinders for Evinrude motors—surfaces 2¼ in. long and 1½ in. wide. From 1-32 in. to 1-16 in. of stock is removed by a No. 17 grinder at the rate of 90 per hour—previous milling time being 60.

**Heat Should Be Avoided**

The work should not be allowed to get too hot, for cold metal always grinds easier than very hot metal. Hot metal in contact with the circle also tends to destroy the bond in the circle, and at this point we again emphasize the advantage of properly designed parts that will carry away the heat generated.



The expansion from frictional heat is seldom evenly distributed through the work and this unequal expansion often warps the part being ground. If grinding is continued while the work is distorted, it is only natural that the ground surface will not be flat when the work has cooled or contracted. In every case avoid hot work, for apart from the above stated disadvantages the parts are not so conveniently handled by the operator.

To minimize the generation of heat, there are certain things can be done. First of all select carefully a sharp, free cutting circle of the coarsest grains practicable, and use sufficient feeding pressure to make these coarse grains bite and cut so that the stock will be roughed off quickly.

If the circle becomes glazed, resharpen it by running a suitable dresser lightly over the surface. A stiff wire brush makes a good tool for such a purpose when grinding carbon, brass, cast iron, etc. The correct feeding pressure to use varies, but the work should never be forced against the circle for more than three to twenty seconds at a time, this of course depending upon the nature of the work. Should the work get too hot before sufficient stock has been remove it is better to handle it more than on allowing it to cool between operatio In the average case, however, especia when the part is properly designed, ov heating does not occur. The three pri cipal methods of reducing the travel grindings are: recessing of patterns, r tating the work and using groov circles.

The importance of breaking up t surface to be ground cannot be ov emphasized. Relieve the finished su face area wherever possible, as by doing you will not only increase prod tion, but will reduce the cost of grin ing, save money on the purchasing circles and make it easier for the op ator. Another point often forgotten that by recessing large castings you a ually save metal, and in some cases t saving in the price of the metal h been known to pay the grinding cos

In a later issue we shall discuss fu ther points to watch for in the art disc grinding, and in the meantime wo suggest you study carefully the exa ples shown throughout this portion the article.

Squaring car brasses on a 26 in. disc grinder. These surfaces are finished straight and true from the roughcasting, so when brasses are clamped in the babbitting fixture, the joints are tight and prevent the babbitt from leaking out. The work does not come in contact with work tables to mar and wear their surfaces. Renewable work holders take all this wear. Time, 20 seconds per surface, from the rough.

Left hand table. Non-rigid. Left hand table carries an ordinary angle plate. Work is located and supported, without clamping, by four studs projecting from face of angle plate; three of which appear in the cut. Feeding pressure keeps the work on a three point bearing formed by three studs projecting from face of angle plate. This is the first operation on the casting.

Right hand table. Rigid chucking. Right hand table carries a quick clamping fixture for grinding the end of the brass. This is the second operation. The end must be ground at right angles to the first finished surface and as nearly as possible at right angles to axis of the brass. Therefore, rigid chucking is desirable to secure accuracy in angularity. Work is located by three studs projecting from top of work holder and is clamped rigidly by means of quick-acting cam lever shown.

# Jigs and Fixtures Used in Making of Truck Parts

## Fixtures For Certain Parts of Truck, These Including Engine Front Support Arm—Tail Lamp Bracket—Water Pump Body—Radiator Front Support Bracket—Tow Hook and Shaft Sprocket

By ROBERT MAWSON

THE workmanship entering into the manufacture of a truck for commercial purposes has to be of the very best. Interchangeability is absolutely essential in order to reduce the assembling time to a minimum, intensive manufacture being, after all, a secondary consideration. The article to follow covers a description of various jigs and fixtures used in the manufacture of trucks manufactured by the Northway Motors Corporation.

The illustration, Fig. 1, shows the machining of the engine front support arm. The casting is placed on the two pads A and forced against the locating stop pin B with a screw at the opposite end. The pin headed screw C is next tightened to force the piece down on to the pads A. Three straps D being tightened as shown, hold the support arm securely in the jig. The tool is first placed on the machine table resting on the four pads E, when a 1-inch hole is drilled and reamed, afterwards being counterbored, for a part distance, to 1¼ inches.

The jig is then placed in the position shown, and two 21/32-inch holes drilled, the tool being guided through bushings F. It will be noted that the placing and removing of the part in this jig is very simple, the straps swinging clear from the element to be machined so that the operator can slide it in from the front, and yet see that it assumes the correct location before starting to drill, thus preventing errors which might be caused if a closed in fixture was used.

The illustration, Fig. 2, shows the jig used when drilling the tail lamp bracket. The forging is located between the two pins A, and a stop in the cover of the jig. The special nut B is then tightened, and the pressure exerted forces the strap shown on to the part and holds it securely. It will be noticed that the strap is provided with an adjustable screw C, which can be regulated so that the strap will rest parallel on the piece being machined. When the bracket is in the position shown, two 5/16-inch holes are drilled, the tools being guided through the bushings in the jig cover. To remove the part, the special nut is screwed off the stud and the strap swung back out of the way.

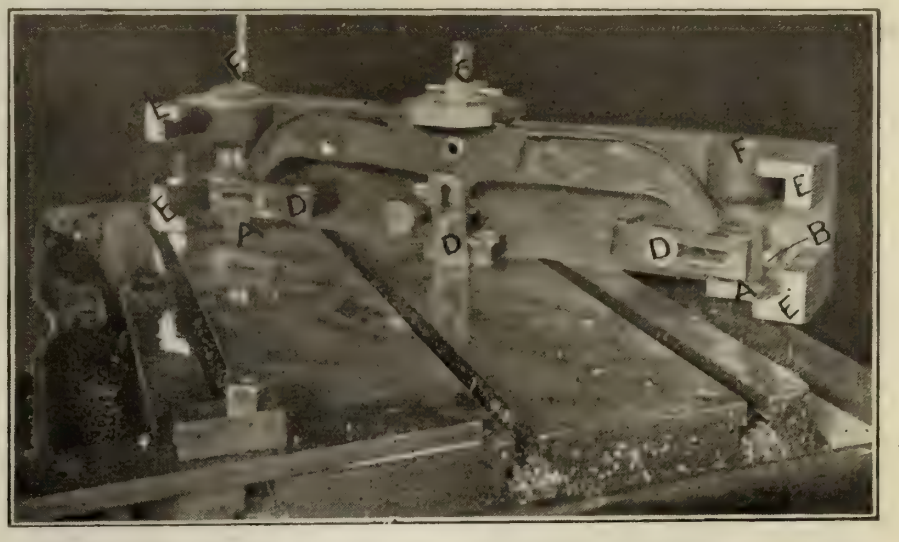


FIG. 1—MACHINING AN ENGINE FRONT SUPPORT ARM.

### Drilling the Water Pump Body

The jig used when drilling the water pump body is shown in Fig. 3. The casting is located by means of a raised projection on the jig which fits into a machined recess in the casting. The pin headed screw A is then tightened, and this forces the piece back against the stop B. The wing nut C being tightened on to the screw as shown holds the casting securely in the jig for the machining operation. The tool is then placed with the surface D resting on the machine table, and two 5/16-inch holes drilled. The jig is then turned over and six ¼ inch holes are drilled in the pump body, using suitable bushings.

A rather simple jig is used for drilling the tow hook, this being illustrated at Fig. 5. The interesting feature of this tool is the method of locating the piece. The hook end of the forging is placed in the hardened steel vee block A, and the other end is set into the steel vee block B, the knob C is then tightened, and as the screw motion forces along the block B the forging is not only centred between the two blocks, but also held in the proper location. Two 9/16-inch holes are then drilled.

The illustration, Fig. 6, depicts the jig used when drilling the radiator front

FIG. 2—DRILL JIG FOR TAIL LAMP BRACKET.

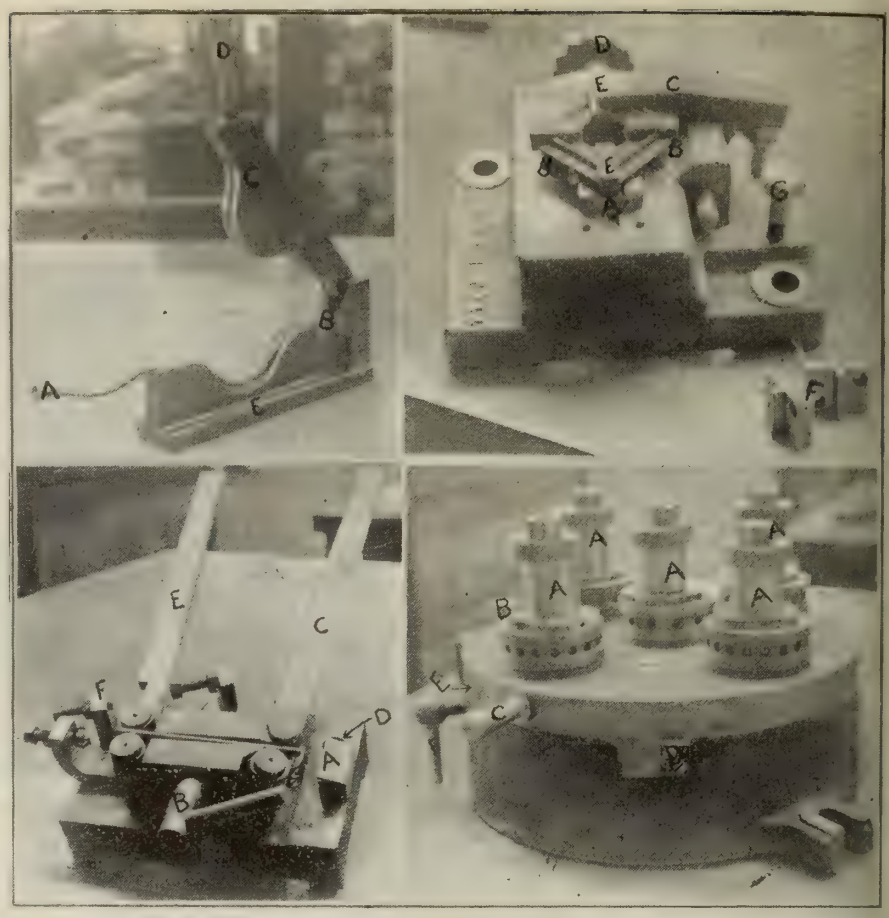

FIG. 3—DRILL JIG FOR WATER PUMP BODY.

support bracket. This casting has been milled on the joint surface in a previous operation, and is then located in the fixture shown by means of two lugs A, one on each side, and two pins placed to form a vee at the left hand end. The cover B is dropped down and held with the swinging bolt and knob nut C. The two knobs D are next tightened and these operate screws that come in contact with the casting and force it back into the proper location, holding it securely. Three 13/32-inch holes are then drilled, the drill being guided through the bushings E and F, and another placed opposite the latter.

### Two Bending Fixtures

A somewhat simple type of bending fixture is used when making the oil relief valve tube; this is shown in Fig. 7. The tube used to make the element is made of copper, and is purchased by the company to the correct size. It is then cut to length, the two ends threaded, and couplings attached as at A. The other coupling is placed in the locating block B, with the tube resting in the slot of the fixture. The cover C is dropped down, and the man pressing down on the handle D can exert sufficient pressure to bend the tube until it takes a similar contour to that of the fixture. The base of the tool E is held in the jaws of an ordinary vise. One of the finish formed parts is shown in the slot of the fixture.

The fixture employed when bending the spark control rod is illustrated in Fig. 8. The rod is first cut to the correct length and located in the fixture by means of a block placed between the inner end of the stop A, and the end of the rod. The holding vise is then tightened on to the part by means of the screw and handle B. The bending handle C is next pulled over, and the end of the rod formed, the handle being drawn down until it comes in contact with the stop D. The handle E is now pulled down until it touches the stop F, and the other end of the rod is bent. It will be observed that the bending levers are provided with hardened steel rollers on both sides of the rod being bent. With the use of these rollers the operation is much easier for the man, less pressure being required, and also the formed portion is much smoother, kinks on the surface of rod being prevented. This tool is also used for bending a longer rod and when adapted for this operation the screw G is used as the locating medium. It will be seen that this tool is very simple in its construction, yet accurate parts are produced, its manipulation is simple, and it leaves little or nothing to guess work or trial.

### Interesting Milling Fixture

The illustration, Fig. 9, depicts a milling fixture used when machining the accelerator shaft floating member. This casting is located on two steel blocks A, the other being at the far side of the tool and resting on two height pins B The strap C rests on top of the piece a one end as shown. The knob D is then tightened and as the slot in which the blocks fit is machined on a taper, a the screw is tightened the blocks are forced upward against the casting, thu holding it firmly in the fixture. A key way is then machined in the arms E the cutter being located by means of th edge of the strap. The casting is the revolved around 180 degrees, and th operation repeated. The casting is nex reversed and located in the tool b means of the steel blocks F, which hav been substituted for the blocks A. I will be observed that these latter block are provided with a tongue, this fittin in the keyway of the casting machine in the previous operation. The piece i held in a manner similar to that alread described, and the four keyways ma chined on the other sides of the arm making in all eight slots. It might b added that another guide strap is some times used on the bolt G to insure ac curacy in the alignment of the keywa cutter.

The fixture shown in Fig. 10 is em ployed when machining the accessorie shaft sprocket, the fixture being de signed to mill five pieces at one setting

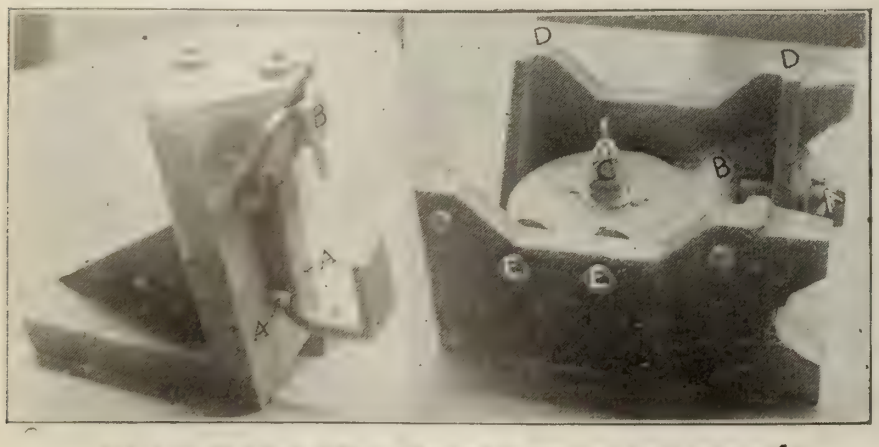

FIG. 5—LEFT HAND VIEW. SIMPLE JIG FOR DRILLING TOW HOOK.
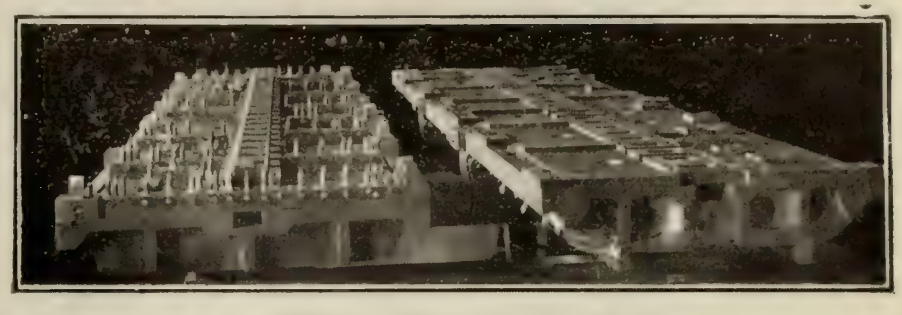
FIG. 6—RIGHT HAND VIEW. DRILL JIG FOR RADIATOR FRONT SUPPORT BRACKET.



hese are located by being placed on the round pins A and held in place with ıe nuts shown at the upper end of the prockets. For the operation of machin-ıg, four cutters are used, being accu-ıtely spaced on the machine arbor. he fixture is then fed under the revolv-ıg cutters in the usual manner, being ıstened on the machine table and lo-ıted by means of keyways in relation ) the cutter arbor.

After two sides of each element have een machined, the fixture is indexed round by means of the pin B, which s withdrawn and placed into another ıcating bushing in the fixed member of he fixture, using the handle C to revolve ıe sliding part of the tool. Guide stops ), the other being at E, are attached to he fixture to assist the operator in de-ermining the positions of the locating ushings.

The crank handle F is then turned, nd this operates a screw coming gainst the sliding member, and assists ı holding the fixture rigid during ma-hining operation. The other surfaces re then milled on the sprockets, mak-ıg four machined faces on each element, s shown by the pieces in the fixture hich have been completed.

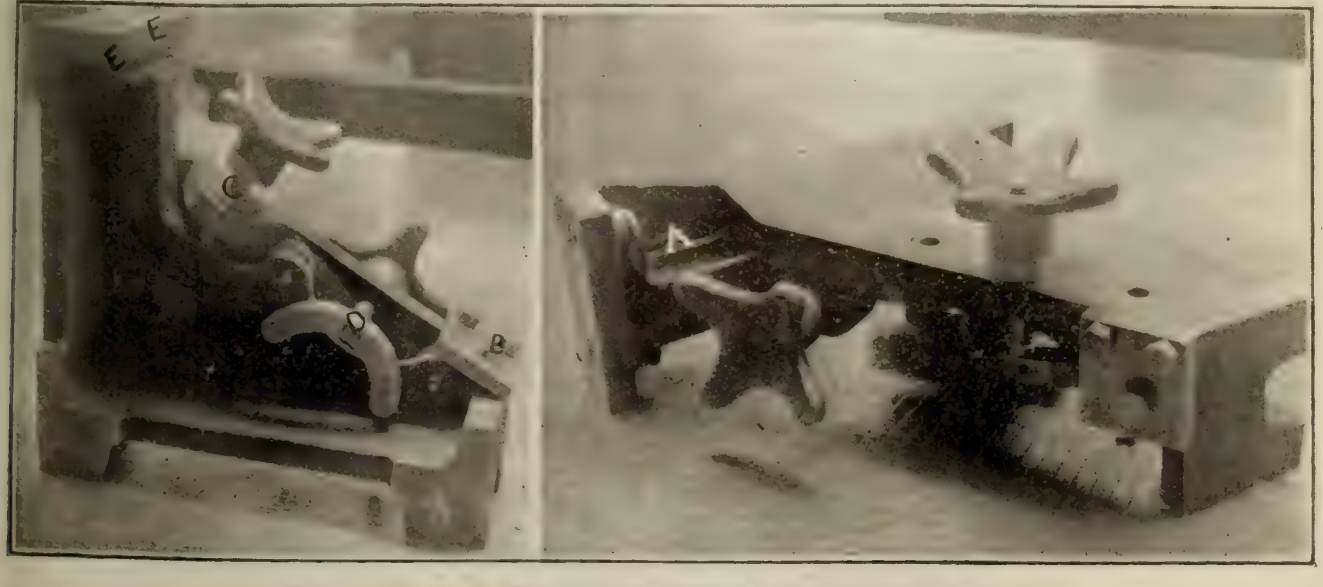
The illustrations, Figs. 11 and 12, how the jig used for machining the uffler front bracket. The casting is laced in the tool and slid over against he fixed stop A. The knurled head crew is tightened, and the pressure xerted holds the piece in contact with his locater. The screw C is adjusted y means of the knob, and this also orces the element against the stop pin. The special hook strap D is afterwards astened in contact with the bracket asting by screwing the knob at the rear n to the threaded stud which is made ntegral with the strap. These three lements therefore serve the dual pur-ose of forcing the casting in contact ith the locating stop pin and also olding it rigidly for the machining operation. Two 13/32-inch holes are drilled, the tool being guided through the bushings E. The jig is then turned over on the machine table until it assumes the position shown in Fig. 12, when two ⅜-inch holes are drilled.

It will be observed that this jig is of open construction, and the operator can see at once if the part is correctly located without any chance of error. Open jig construction is a good design to follow if at all possible.

GENERAL APPEARANCE OF THE DIE.

## SEED DRILL DIE

By TRACEY MANES



A very interesting die is shown in the accompanying illustration. This depicts a punch die, used in the Massey-Harris plant at Toronto, for producing the hopper for seed drills. The complete die is 34 inches wide, and 144 inches long; 380 punches of various sizes are used, these ranging from 7/32 inch diameter up to 4-inch by 2-inch section, with semi-circular ends. The punches are 2½ inches long, while the die insert blocks are 1¼ inches thick. The hoppers were produced on a W. & W. press, the stock being 1/16 inch thick.

A special feature on this die is the fact that it produces seven different combinations. By removing, or adding, punches as the case may be, seven different hoppers, known technically as the 8, 12, 14, 16, 20 and 22 respectively, can be punched out with the same die. Out of the 380 punches, 96 are 7/32-inch diameter; 7/1000 clearance per side was allowed in the making of the die.

## CLAY FOR LOADING PAPER

A highly colloidal clay which exists in large deposits in the intermountain regions of the United States has been found by the United States Forest Products Laboratory to be valuable as a loading material for giving finish and printing qualities to book paper. When this clay is used in conjunction with English china clay, the retention of the English clay is materially increased, and the paper produced has a superior finish and appearance, and a more velvety feel. The admixture of this clay similarly improves the retention of other fillers, and is especially desirable with some which have a low retention.

The ability of the new clay to remain in suspension may make feasible the installation in paper mills of a central mixing plant, from which the loading material can be piped a considerable distance to the beaters, without danger of setting or clogging of the pipe lines, and with the assurance that the concentration will remain uniform. The properties and use of the new loading material are more fully described in a report which may be obtained from the laboratory on request.—Scientific American.

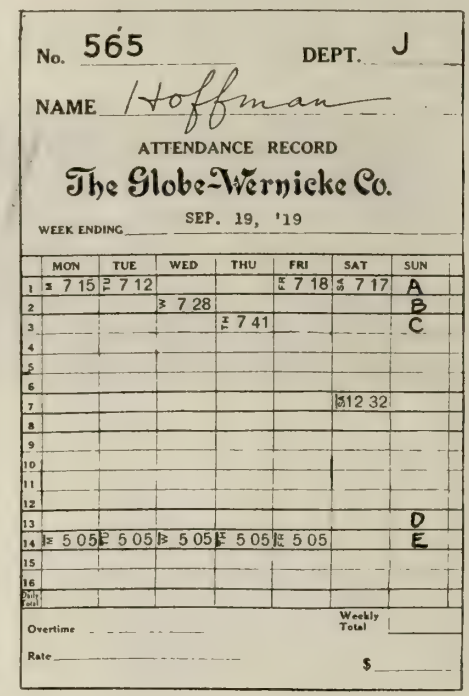
# The Determining Factors in Any Industry



## Time the Factor to be Considered—Any Time-recording System If Used Effectively Benefits Employer and Employee—One Method Employed Includes Special Inducements to Workers

MOST concerns engaged in manufacturing have come to realize that time is the element upon which depend all costs and all production; time is always working. When used effectively throughout a manufacturing plant it is working for both the firm and the employee, but when wasted or misspent the result is an increase in labor cost and overhead expense; in other words, a loss of production and profit to both employer and employee. When profits consistent with the amount of capital invested are not forthcoming, a manufacturing enterprise loses its attraction and incentive and eventually operations must be discontinued. As a matter of fact, the use of time and how it is accounted for are the determining factors in the adjustment of any industrial plant to conditions which prevail to-day—namely, increased labor and material costs, shorter working hours and keen competition.

To account for every factory worker's time at the plant and to know just how much of it is spent productively on various jobs and operations is indeed a problem, especially to those engaged in operating woodworking establishments. A practical and effective solution which has been adopted by many large manufacturers consists of an installation of modern time-recording equipment.

If you wish to run a plant smoothly with every job or operation planned in advance and scheduled so that all departments will correlate perfectly; to keep a check on the factory to see that it does not lose time by waiting of one department for another for delivery of parts, raw material, etc., to know exactly how much time is being spent by each department productively and non-productively; to know exactly how each operator's time is divided between various jobs and whether or not his work is up to standard of production; to know just how much was day work and how much piece work or bonus time, etc.; to know just how much wages each employee is entitled to; to determine accurately the cost of every part or article manufactured; then to do all these things accurately, impartially and inexpensively, you must have some form of time-recording. The Globe-Wernicke Co. decided to install a time-recording system, and this story tells of the method employed.

They installed a complete Stromberg electric automatic time system, this consisting of sixteen "in-and-out" time recorders, forty job time recorders, sixty secondary or wall clocks and a system of factory signal horns and bells, all operated electrically from a central master clock.

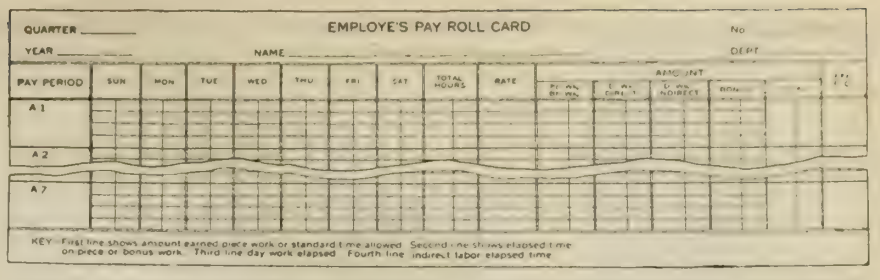
The master clock is automatically wound by the same electrical current that operates the recorders, clocks and signal horns. Since this is the only clock works in the entire system, and as the secondary units are automatically regulated by it, perfect synchronism of time is obtained throughout the plant. The recorders and other secondary apparatus, not having any delicate clock works, but being driven instead by powerful electro magnets, operate under any condition of dust, vibration, varying temperature or abuse, with practically no maintenance or repair expense. Electric current for operating the system is supplied by batteries which are automatically charged from the regular 220 volt electric light current.

### Attendance Records

A record of the exact time of arrival and departure of employees is made at the "in-and-out" recorders. Railings around these recorders, and aisles leading past each one, serve to prevent confusion and crowding at registering time. Each employee has a weekly attendance card like that appearing in Fig. 1. These cards are kept in the numbered pockets of convenint "out" racks near the 'in-and-out" recorder, while the employee is not on duty. When a workman comes in the morning he takes his card from the "out" rack, inserts it in the recorder and by pressing a lever, stamps the exact time on it. He then places it in a similar "in" rack near the foreman's desk, where it remains until he is ready to ring out at night. By having these cards so filed close to the foreman's desk, the foreman is able to determine at a glance how many employees have not reported for work, and thus he can rearrange their work and plan the day's operations accordingly. The cards can be used for ringing out and in at lunch also, but this practice is not followed at the Globe-Wernicke plant. The lunch period is only a half-hour and most of the employees eat lunch at or near the plant.

As an inducement for every employe to be in his respective department and on the job full time, the company adds an hour to the day's pay of every workman who registers "in" on or before 7:20 a.m. — ten minutes before actual starting time—and "out" on or after 5:05 p.m.—five minutes after actual quitting time. There are many advantages in this plan. While it does not exactly penalize the individual who prefers to register in and out "on the dot" or carries barely enough margin of time to avoid being docked for lateness, it rewards those who are willing to get in a few minutes early and remain a few minutes late in order to be in working togs and engaged in productive work the full nine hours. An hour's bonus pay for fifteen minutes' extra time is of course equivalent to quadruple pay for that period. This plan also has the effect of preventing over-congestion at registering time.

In order to make it easy for the pay roll clerk to readily distinguish between different registered time entries—those ten minutes or more early, those barely on time, and those late—the recorder is adjusted to print each class on a different line on the attendance card. At exact



7:20 a.m. the mechanism automatically changes so that all registrations before that time appear in space No. 1 on the card, Fig. 1, and after that time they appear in space No. 2. At 7:30 there is another change so that late arrivals are registered on space No. 3. A similar automatic classification is made at ringing-out time. The recorders automatically set themselves to the proper "in" and "out" spaces for all classes, and also automatically distinguish tardiness and other irregularities of all employees. This plan greatly facilitates the work of the pay-roll clerk in taking off time from the attendance record cards and entering it on the employee's pay-roll card, Fig. 2, as he need only deal with the exceptions.

### Job Time Records

The starting and stopping time of each job is stamped on work-order and time card (see Fig. 3) with job time recorders. These recorders are distributed throughout the various departments of the plant. The work-order time cards are compiled from current cutting bills and operating records, by the departmental planning clerk, and filed in proper rotation in pockets (there being a pocket labeled for each machine in the machine department) on the dispatch board. When a workman presents his attendance card in the morning, he is given a work-order time card, which is then stamped with the starting time on the recorder. When the operation designated on the card is completed the workman returns his card to be stamped with stopping time and gets another job card. This routine continues just like clock-work throughout the day, and at quitting time the last card is turned in and stamped, regardless of whether or not the operation is finished. If unfinished, the space under "continued" in the lower left-hand corner is check-marked and a new card is issued next day for the completion of the operation.

Up-to-date unit standards of time for all operations are kept on file at the desk of the planning clerk. The unit standard for the kind of work designated is entered in the proper column of every work-order time card, and by multiplying this by the number of pieces or units in a run, the total standard time is found. Thus in Fig. 3 the unit standard is marked 1.5, meaning 1.5 hours per thousand. Multiplying the number of pieces on the ticket (800) by 1.5 gives 1.2 hours as the standard time allowed for the task. Referring to the registrations of the job time recorder, it is evident that the time elapsed (5.2 minus 4.0) is 1.2, which shows that on this operation the workman attained 200 per cent. efficiency, and, according to present rules, is entitled to a 20 per cent. bonus. Bonuses on production start at 67 per cent. and gradually increase with the percentage of efficiency.

FIG. 2—UPPER VIEW. THE PAY ROLL CARD USED.
FIG. 3—LOWER VIEW. WORK ORDER AND TIME CARD.

job time recorders is that they automatically eliminate the lunch period from all jobs that start in the morning and finish after noon, so that clerk need not make any deductions from the time shown on the job ticket for the lunch period. As an example, the recorders print 0.0 at 7:30 a.m., which is starting time in the morning. At 12:00 the recorders print 4.5 and then are automatically suspended until 12:30, when they again automatically start up with 4.5. So, a man starting a job at 7:30 a.m. and finishing it at 3:00 p.m. will register as follows:

| | |
|---|---|
| Stop | 7.0 |
| Start | 0.0 |
| Elapsed time | 7.0 hours |

The clerk needs merely to make a simple subtraction, without the necessity of deducting the lunch period. The simplicity of calculating time in this decimal scheme is also valuable.

The information and records obtained from work-order and time card are summed up and entered on the employee's pay-roll card (Fig 2) and on the piece-part cost summary as well as on other cards, including piece-part-progress records, etc.

It will be noticed that on each work-order time card there are spaces for four order numbers on jobs. This is done to permit of bunching two or more jobs and running them all at one time when possible. Every lot of parts on a job going through is identified by a tracing tag like that shown in Fig. 6. These tags are placed with the various batches of material when it is cut by the stock-cutters, and they follow the material through all the machine operations, remaining with it until it is transferred to the assembly department. When any set of parts leaves the stock sawyers it is up to the planning clerk to route the work from then on, assigning it to various machines and machine operators by schedule.

### Secondary Clocks

The secondary or wall clocks indicate the same accurate time as the rest of the time system equipment and are so located as to be seen by practically every employee.

Careful observation has proved that employees will ascertain the time of day, if not by a mere glance at the wall clock, then by walking over to a neighboring employee who is known to have a watch. This usually leads to a more or less lengthy conversation with the result that both employer and employee are losers in production.

It is highly important that the secondary clocks be exact in time and agree with other time equipment. An entire department of fifty employees might lay down their tools and prepare for quitting a minute too early, if their department clock is one minute fast. Thus, a total loss of fifty minutes, at noon and again at night, would be occasioned.

The Canadian Des Moines Steel Co., Chatham, Ont., has been awarded the contract for the construction of elevated steel tank for York Township Council.

---

The Welland Machine and Foundries Ltd., Welland, Ont., as a result of the recent organization, will operate under the management of William Edestrand, who at one time was with the Dain Mfg. Company.

# WELDING AND CUTTING

# Selection of Gas Welding Apparatus for Economy

## Blowpipes Should Be Selected According to Requirements of Work, Consideration Being Given to Economy, Etc.—How to Overcome Backfiring—Job and Production Work Differ Widely

By F. W. SMITH*

OXY-ACETYLENE work in general is peculiar in that in all cutting and in all but the lightest welding, the cost of the fuel gases, oxygen and acetylene, is greater per hour than the cost of the labor of the operator even at the present high price of labor. This can readily be computed from the cost of oxygen, two cents per cubic foot, and acetylene, one and a quarter to three cents per cubic foot, and the fact that the lightest cutting ordinarily done consumes over 35 cubic feet of oxygen and 15 cubic feet of acetylene per hour, while welding of anything as heavy as 3/16-inch steel plate will consume at least 15 cubic feet of each gas per hour.

Too much weight, therefore, cannot be given to the economical operation of the blowpipe as regards gas consumption and it follows that it is also economical to hire a very high class of labor and to keep this labor well satisfied in order to secure co-operation in the economy of fuel gases.

Welding consists of two separate operations, one the raising of the temperature of the work to welding heat and the other the application of the filler rod, flux, mechanical pressure or such other means as may be necessary to supplement the heat from the blowpipe to secure a satisfactory weld. It should be recognized that the function of the blowpipe is that of heating alone. If the blowpipe does the heating economically as to gas consumption and conveniently from the point of view of the operator, its entire duty has been performed. The rest is up to the operator and his supplies and mechanical equipment.

### Must Align Seams

For instance, in steel tube welding, where no filler rod or flux is used, the success of the process depends on the blowpipe only in so far that the flame must be sufficiently hot to bring the edges of the seam to a welding heat as fast as it is desired to weld and that this must be done with an economical consumption of gas. Of equal importance and more difficult to attain is an exact alignment of the edges of the seam with each other under the blowpipe. For this alignment accurate forming of the tube, previous to its introduction into the welding machine, is essential. To secure a weld of the proper penetration and thickness, it is further necessary to adjust accurately the compression on the welding rolls which force the edges of the seam together after they have been heated.

In the case of hand welding, where filler rod and possibly flux are to be added, inexperience or carelessness on the part of the operator may cause cold shuts or blow holes in the weld quite independent of the efficiency of the blowpipe.

These examples are sufficient to establish the contention that the function of the blowpipe is merely to supply heat and that no blowpipe, however perfect, can guarantee a satisfactory weld without the necessary adjuncts of a good operator and accessory equipment.

The first consideration in regard to any blowpipe should be its heating efficiency. The transference of heat is dependent on two factors, the difference in temperature between the flame and the work, and the length during which the gases are in contact with the work. Since the temperature of the oxy-acetylene flame is the same in all blowpipes, the heating efficiency will depend entirely on the length of time the burned gases are in contact with the work. The time is determined by the speed of the gases issuing from the blowpipe tip. Therefore, the first necessity in a blowpipe is low velocity of the gases at the tip or, as the welder generally phrases it, "a soft flame." Velocities from 300 to 350 feet per second are found by experience to be the lowest practicable and the heating efficiency of the blowpipe depends upon how closely its gas velocities approach these values.

### Testing Method

To test the blowpipe for this quality the most reliable and scientific method is to run accurate gas consumption tests on the blowpipe and by dividing the sum of the volumes of the two gases by the area of the hole in the tip, to secure a figure which will represent very closely the gas velocity desired. The experienced welder can, however, tell almost immediately by looking at the flame what its character is, and a very reliable test is to attempt welding steel overhead or on a vertical seam where it will be found that the molten metal can be controlled satisfactorily only with a soft

#### REGARDING THE BLOWPIPE

It should be recognized that the function of the blowpipe is that of heating alone. If the blowpipe does the heating economically as to gas consumption, and conveniently from the point of view of the operator, its entire duty has been performed. The rest is up to the operator and his supplies and mechanical equipment.

In hand welding, where filler rod and possibly flux are to be added, inexperience or carelessness on the part of the operator may cause cold shuts or blow holes in the weld, quite independent of the efficiency of the blowpipes.

This proves that the function of the blowpipe is to supply heat only, and that no blowpipe, however perfect, can guarantee a satisfactory weld without the necessary adjuncts of a good operator, and accessory equipment.

*The author was formerly chief engineer at the Oxyweld Acetylene Co., Newark, N.J., and his article first appeared in the Iron Trade Review.

flame. This consideration is given first importance because it applies to every job regardless of size or character.

The subject of backfiring is of great importance. In the beginning of the industry, when the majority of welding work was done under accidental and generally adverse conditions, backfiring was one of the greatest difficulties encountered and consequently great value was attached to a blowpipe which would not backfire. Backfiring is the burning of the gases inside of the blowpipe. Such an occurrence stops the welding process immediately and, if allowed to persist, will damage the blowpipe irreparably. It is then necessary to close the oxygen valve and relight and readjust the flame.

Backfiring is caused either by overheating the blowpipe to such an extent that the mixed gases ignite from the heat of the passages in the interior of the tip or head, or by the obstruction of the tip by touching the molten metal or slag which so slows up the mixed gases that the flame will burn back against their current into the interior of the torch. It will readily be seen that in modern production welding the adverse conditions which cause backfiring are practically entirely eliminated by the convenient location of the work and the high skill developed by repetition. Even in the hottest emergency repair jobs backfiring can be minimized by water-cooling the blowpipe and is, in any case, comparatively infrequent with a properly trained operator.

While backfiring was an important consideration in the early stages of the art, present day developments have relegated it to a far less important position. The criticism aroused by backfiring has resulted in the appearance on the market of numerous blowpipes which do not backfire even under the most severe conditions. On the other hand, it is found that this non-backfiring feature frequently is attained by the sacrifice of the low velocity of the gases and in consequence such blowpipes should be tested very thoroughly for welding efficiency.

Welding logically divides itself into two branches, quantity production welding and job welding and for these branches different considerations govern.

For job welding, the principal considerations are reliable and satisfactory operation and flexibility so that jobs of widely various character can be handled with the minimum of investment in equipment.

The question of the reliability of various makers of apparatus is one not properly to be dealt with in this article but the purchaser should bear in mind that, in regard to durability, exactly the same considerations will govern oxy-acetylene apparatus as any other equipment. He should picture to himself not only what will happen to each part in the correct course of operation but also how easily they may be damaged by accidental happenings which are unavoidable in every sort of mechanical work and especially in the rough and ready repair jobs such as are encountered in job welding.

### Strength Is Necessary

All parts such as valve stems, hose connections and union nuts should carry sufficient weight to be structurally strong and complicated mechanisms should be avoided above all things.

Tips and other detachable parts are subject to more damage and loss when not in use and lying loose in the tool box than when actually attached to the blowpipe. Tips having joint surfaces exposed so that they will be marred by accidental dropping or rattling against each other are to be avoided unless the operator can be trained under all circumstances to carry these tips in racks or other cases which provide the necessary protection.

In this class of work it pays to anticipate the worst possible conditions as the operator must frequently travel some distance to get to the job and there is usually a premium on finishing as rapidly as possible. Nothing will give the shop a black eye as quickly as to have a delay because of some minor fault in the apparatus.

In regard to flexibility, it may be assumed that a welding blowpipe which will burn approximately 70 cubic feet of each gas per hour will do the heaviest welding which it has been found practicable to attempt. For this class of work a torch of considerable length is required because, owing to the intense heat of preheating fires usually used, the operator cannot stand very close to the work. If work of this character is to be undertaken, this special large sized torch is desirable. For all other lighter classes of work, where consumptions vary from 40 cubic feet downward, usually a single blowpipe 18 inches in length can be made to cover the entire range by the use of tips of assorted sizes. Unless the shop is of sufficient size and has sufficient steady trade to guarantee a steady flow of jobs, both large and small, blowpipes of this nature should be used. As the business broadens out and certain lines are definitely established, it will always be possible to purchase other equipment which will render the handling of such particular work economical.

Production welding is of only recent development and its possibilities are little realized. It is entirely different from job welding in that it assumes a year-in-and-year-out demand for an article which can be produced wholly or in part by the welding process. For such a demand, elaborate plans and arrangements can be made, such as convenient benches and seats for the operators, jigs and handling devices for the work, specially designed blowpipes and light hose.

The question of flexibility in the apparatus enters only to a very slight degree as the work will probably be confined to one weight or gauge of metal and the blowpipe should operate for long periods of time without changing the tip or making other adjustments. Most of the accidental damages are entirely eliminated and a much less rugged type of apparatus in general can be considered. In fact, the proposition often resolves itself into one of time study operations done by specially trained men or girls using equipment arranged with only this operation in view.

The purpose of a regulator for welding is to reduce the high pressures at which compressed gases are supplied to the trade to pressures suitable for use in blowpipes. Regulators are probably the most difficult of all oxy-acetylene apparatus to manufacture and it is believed there is no regulator on the market which can be guaranteed to work reliably for a considerable period of years. The very high pressures which they are required to handle render leaks and erosion very difficult to combat and the impossibility of preventing dust and small grit from being entrained in the gases and getting into the regulator seat, make it only a question of time when the regulator will begin to leak. The result of these leaks is the building up of pressure in the hose as soon as the blowpipe is shut off, resulting in the blowing off of the hose with attendant dangers.

### Pressure Decrease Important

In the case of acetylene regulators, this feature is particularly objectionable as the limit at which free acetylene can safely be worked is about 30 pounds. In acetylene regulators also the amount of drop or decrease in delivery pressure when the blowpipe is turned on is of

### BACKFIRING. HOW TO AVOID IT

Backfiring is the burning of the gases inside of the blowpipe. It is caused either by overheating the blowpipe to such an extent that the mixed gas ignite, or by the obstruction of the tip by touching the molten metal or slag, which so slows up the mixed gases that the flame will not burn back against their current into the interior of the torch.

This trouble however, is not very wide spread as modern torches are much better constructed than formerly. Even in the hottest repair jobs backfiring can be minimized by water cooling the blow pipe. With a properly trained operator, backfiring becomes an easy matter to overcome.

Preference should be given blowpipes which have full, long preheating flames, calculated to operate entirely across the face of the intended cut.

considerable importance since the working pressure of acetylene is limited by fire underwriters' regulations to 15 pounds. It will readily be seen that if the drop from 15 pounds is 7 pounds, there will be only 8 pounds pressure left on which to operate the blowpipe and this is prohibitive in case the blowpipe requires a higher pressure. The drop measures to a certain extent the freedom of the moving parts and the tightness of the regulating valve.

The prospective user of acetylene should make up his mind to purchase the best regulators and only the best and to establish a careful system of maintenance on them, to keep them in good order. Periodical monthly inspections followed up by thorough repairs of any faults detected are the best methods of accomplishing this and in the initial purchase the customer should be governed by observation of the performance of the regulator during tests, its freedom from leakage when the blowpipe is shut off and convenience for repair when leaks develop. He should also give consideration to the mechanical construction of the regulator, especially the method of suspension of the moving parts since the sensitiveness of the regulator should be governed largely by the freedom of these parts.

In most cutting, much the same considerations govern as in job welding. In other words, reliability and flexibility are at a premium. Even in steel foundries where the cutting of risers is a regular step in the production of steel castings, the work can hardly be arranged in any way which will not subject the apparatus to the roughest sort of usage. Durability is the first consideration in cutting apparatus.

In heavy cutting large quantities of gas, as high as 1,500 cubic feet of oxygen and 50 cubic feet of acetylene per hour are used. Economy of operation in the blowpipe is a feature of special importance. Before selecting apparatus for work of this kind, consumption tests of the most elaborate nature should be run, preferably on the actual work. It will be found from such tests that a blowpipe having very ample preheating flames will accomplish the start, the most difficult part of the operation, far more rapidly than if the preheating flames are limited in size, and that the whole process is speeded up by satisfactory preheating. Preference should be given blowpipes which have full, long preheating flames, calculated to operate entirely across the face of the intended cut.

The oxygen regulator for this class of work should be designed with especially large passages, as otherwise, due to the rapid expansion of the oxygen discharging from the cylinder, there is a tendency for the regulators to freeze and clog which, of course, puts an immediate stop to the work. In heavy cutting also it not infrequently occurs that the pressure in the cylinder runs from the original 2,000 pounds down to almost as low as the working pressure of the blowpipe. In this case many regulators show a marked drop in the operating pressure during this change in the cylinder pressure. Such regulators will be unsatisfactory for heavy cutting.

### Speed Is Required

Light cutting presents usually no features not found in heavier work except that it sometimes occurs as a production proposition and in this class of work the same conditions govern to a certain extent as in production welding. There is, however, one phase of light cutting very widely practised in shipyards, namely, the burning out of countersunk rivets and piercing of blind holes where special conditions occur which must be considered. As most countersunk rivets are burned out in repairs, speed is the first consideration. Furthermore, the conditions under which the blowpipe must operate are very adverse. Slag from the burned rivet frequently falls directly upon the blowpipe and the preheating flames beat back upon it from the blank surface with great intensity. Under these circumstances backfiring occurs with such frequency and is so inconvenient to the operator that it entirely outweighs the considerations of gas economy and here the non-backfiring blowpipe is a necessity.

Oxygen is supplied to the trade generally in cylinders of 200 cubic feet capacity at a pressure of about 2,000 pounds. Acetylene can also be had compressed into cylinders of 100 or 300 cubic feet capacity at pressures of 225 pounds. These cylinders are practically the only source of acetylene available for jobs outside of the shop. Where the work can be done in the shop, however, it takes only a comparatively small consumption of acetylene to justify the purchase of a generator. Acetylene can be generated from calcium carbide at about half the price at which it can be purchased in cylinders. There is also usually a considerable initial payment attached to the use of acetylene cylinders themselves.

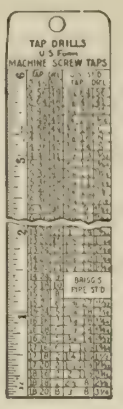
# The Danger of Using Unknown Scrap

IN speaking of the scrap dealer who purchases old metal tanks, barrels or cylinders, Acetylene Journal emphasizes the necessity of ascertaining definitely the uses to which such containers have been put. They continue:

If they have held combustible gases or liquids or even certain dry chemicals they are a serious source of danger.

The following case, which is by no means an isolated instance of the kind, illustrates the point. At a certain Ohio scrap yard some weeks ago an explosion resulted in the death of a workman who was cutting bolt holes in a piece of angle iron. In order to make the work accessible he placed it on a sheet steel drum about three feet high by two feet in diameter. Unintentionally he penetrated the steel sheet of the drum, causing the violent explosion of an unsuspected gas which it contained. Both ends of the drum were blown out, one of the ends and several pieces of angle iron striking the victim of the accident, breaking four of his ribs and puncturing his lungs with fatal effect. An inspection of the drum showed that it had been airtight and had contained a substance resembling sulphur. The dealer stated that he had purchased several of the drums as scrap material some three years previously, and had no idea as to what they had contained.

In many cases the former use of the container may not be suspected, but there are several other instances where it should be obvious to a dealer in scrap. For example, everyone engaged in the production of scrap should recognize instantly cylinders used for the storage and transportation of compressed gases. Such cylinders are usually the property of the companies that produce the gases so stored and transported, and their names are generally conspicuously marked on the container in a manner difficult to efface--commonly by stamping the metal with a die.



Whenever tanks that have been used for explosive gases, liquids or substances are offered for sale as junk, the person offering them should be advised as to their character and warned not to dispose of them for reduction; and the nearest office of the manufacturer, whenever the name is obtainable, should be notified without delay.

### INACCURATE WITH AGE

Thermometers like everything else become old, and consequently lose their accuracy with age, mercurial instruments reading too high and spirit instruments too low. Scientific American speaking on the subject states that in the former case the bulb appears to shrink, thus forcing the quicksilver too far up the stem. This gradual shrinkage is supposed to be due to the fact that the external pressure on the bulb may be considerably higher then the internal pressure, the air as far as possible having been removed before the glass is sealed off. On the other hand, the spirit thermometer is sealed with the bulb covered in a freezing mixture, in order to lock up in the glass as much air as possible. The instrument thus starts with an internal pressure which in time appears to be reduced either by expansion of the glass under the internal pressure or by leakage.

# Improve Your Powers of Perception—Try This Contest

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Nine contestants submitted correct lists to the May 12th contest, these being: F. E. Regan, Hamilton, Can.; E. N. Mills, Montreal; George Meriden, Paris, Ont.; Angus A. Smith, Mt. Forest, Ont.; E. W. Todd, Penetanguishene; George Land, Peterboro; P. O. Nobes, Molton, N.S.; Colis W. Parent, St. John, N.B., and J. P. Gifford, Providence, R.I.

In view of such an array of talent we had to resort to the elimination process, and F. E. Regan was the lucky one. As stated before, we place the correct lists face down on a table, and get some neutral party to select one from the lot. The list selected is the one considered the winner. In this way it is fair to everyone. Should recent winners not be receiving their scales, notify us at once, as some time ago we had difficulty in forwarding them through the mails.

**CONTEST FOR JUNE 2ND ISSUE**

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1—How to get all kinds of a particular product.

2—An organization that is always at your service.

3—Something that was done for you years ago.

4—A list that is merely an indication.

5—Something that will handle any material.

6—A product that assures proper clearance.

7—Something equally suitable for twist drills, circular saws, or machine knives.

8—How to get more work done in less time.

9—Something that requires no pattern.

10—A product produced from 5/8 in. diameter, and smaller.

11—Something that forms a half nut.

12—A concern that asks to shoulder your problems.

**These are Correct Answers for List from May 12th Issue:**

1—Roelofson Machine Tool Co.

2—Union Mfg. Co.

3—J. Ackworthie, Ltd.

4—E. C. Atkins & Co.

5—John T. Hepburn, Ltd.

6—The Dennis Wire & Iron Works Co., Ltd.

7—Lyman Tube & Supply Co., Ltd.

8—Hoyt Metal Co.

9—Armstrong Bros. Tool Co.

10—Canadian Hanson Van Winkle Co.

11—Crane, Ltd.

12—Brown & Sharpe Mfg. Co.

## Closing Date for This Contest is June 23rd

# Hints on Hardening of Hammer Die Blocks

## A Good Sound Steel of Medium Carbon Content, When Properly Hardened, Gives Good All-round Service—Gas Heated Furnace Very Satisfactory for Die Block Work

By R. B. KERR*

SINCE the introduction of the modern drop forging hammer, the problem of producing and successfully heat treating large dies to get the maximum of service with a minimum of loss has engaged the attention of steelmakers and steel treaters alike.

Early in the game it was found that the percentage of loss from hardening from various causes was heavy. Flaws or pipes in the interior of the blocks resulting from improper casting or forging; steel of too high or irregular carbon content; and more especially inadequate tempering room equipment, are among the chief causes of failure. The unfortunate hardener too often is made the goat for the sins, mostly of omission, of both the steelmaker and the shop foreman.

To get around possible loss in heat treating, various kinds of alloy and so-called heat-resisting steels have been tried, with more or less success. Now it is generally conceded, however, that a good sound steel of medium carbon content, when properly hardened, gives the best all round service. The methods suggested herewith for accomplishing this have been in successful use by the writer for a number of years and are offered not with an idea that they are perfection or the only way, but with the hope that they may be helpful.

While die blocks can be heated successfully in either coke or oil furnaces or even in the smith's forge, a gas heated furnace of the oven type is by far the most convenient and satisfactory for this work.

Coke makes a nice clear fire of fairly simple regulation, and with a skillful heater in charge, good results can be obtained. An objection to its use is the frequent presence of impurities, particularly sulphur.

When heating dies the considerable air pressure required to burn fuel oil makes necessary the most extreme care to prevent scaling or surface decarburization in the parts to be treated. The furnace, therefore, should be of the muffle type, the heating chamber completely inclosed, or, if this is not available, the die should for protection be packed face down in a gas tight box of suitable size half filled with charcoal, and the whole thing heated up. If the piece to be heated is of considerable size, the packing box should be made with hinged ends which fold down out of the way so that the die can be lifted out readily by grab hooks or a sling. This "safety first" method entails some extra work and inconvenience, but the results justify it. Personally, the writer can testify through considerable experience that it is better to go to some extra trouble to assure success, than to have an opportunity later on to frame up excuses that will pass when asked to explain "how it happened."

It might be said in passing that this method of pack hardening is excellent for heating dies and tools of nearly all descriptions. The parts come out of the packing box uniformly heated with a surface perfectly free from scale and in the best possible condition for hardening. The process is an old and successful way of heating steel. It deserves to be more widely known and practised.

### Get a Good Heat

Whatever the type of furnace used or the means employed the all important thing is to get a good heat on the die; a thorough slow soaking, uniform heat, for upon that depends to a great extent the success or failure of the operation. Particularly for the benefit of the younger steel treaters it may be said that thorough careful heating, more especially when handling comparatively large blocks of steel, is most essential. It is the author's opinion, based on a long and varied experience in hardening steel, that more dies and tools are ruined by careless heating than from all other causes combined.

For heating, a gas-fired, oven furnace of ample capacity should be used as being most convenient and suitable for the job. If the oven is already hot so much the better, if not, bring it up pretty well before putting in the work. Dies of any description should not be put into a cold furnace. Nothing is gained in time, and besides some chances of surface decarburization are offered with a rapid rising heat.

Place the die in the furnace face down, unless the nature of the impressions makes this impossible; in which event it is good practice to protect the surface from possible gases by laying a closely fitting piece of asbestos or sheet steel on top while heating. As another precaution, if the die is of considerable size and the impressions are deep or irregular, it is well to bring it up to a dull red heat, about 1,300 degrees Fahr., and let it partly cool off in the furnace before taking the hardening heat.

Heat slowly and regularly. The time required of course will vary in proportion to the heating area of the furnace and the size and shape of the piece to be treated. Usually three to five hours are required for drop forging dies of average size. The most important point is, as already mentioned, to get uniform heat throughout the piece. One of the most valuable assets a steel treater can have is the ability to judge or sense correctly when a large block of steel is heated properly throughout. While a pyrometer or other reliable heat measuring device is a valuable aid and guide, it is not everything, neither can it indicate what is going on inside the mass, and the writer has learned from experience that outward appearances in steel die blocks, as in many other materials, are often times deceptive. The average grade of hammer die steel will harden nicely at around 1,450 degrees Fahr. and the heat always should be held stationary for at least 15 minutes before removing the die from the fire.

The quenching tank should be of ample size and the water supply arranged so that it can be forced upward against the face of the die with considerable force and volume, using an overflow pipe of sufficient size to take it away. In most cases clean fresh water is all that is necessary, but if extreme hardness is required or if the water is soft or muddy, river water as an example, the addition of a little salt will sharpen it. If this is done, a loose woven sack filled with salt, and suspended in the tank, will be found most convenient. Place a resting rack across the top of the tank, arranged at sufficient depth so that the impressions on the face of the die will be well covered with water when the die is laid on it. On flat surfaced dies or on dies in which the impressions are shallow, a depth of from 1 to 1½ inches is about right.

When all is ready get the piece out of the fire. If there are any dangerous looking corners or sharp projections that do not need to be hard, partly cool them off with a water jet or piece of water soaked waste to prevent chipping. Place the die on the resting rack face down and turn on the water. If the piece is wide or flat, prevent warping or crowning by keeping the back slightly cooled off; just enough water and no more. Run the hand over the face frequently to find how it is cooling off.

### A Point to Watch

Never let a die cool off entirely in the water. Whenever the face is cool enough to prevent the temper from

*Presented by title before the Convention of the American Society for Steel Treating.

drawing, get it out as quick as possible and lower it into the oil tank. Keep the die moving or agitate the oil.

The temper should be drawn slightly on all hammer dies, both to relieve strains and to give them resiliency or spring, as well as for better wearing qualities, and the drawing should be begun immediately; even before the die is quite cooled off. If there is an oil tempering furnace at hand large enough, get the piece into it. Raise the temperature to around 400 degrees Fahr. and hold it there for an hour or so. If for any reason this method cannot be used, swab the die with light machine oil and place in a furnace partly cooled off. Leave it there until the oil begins to flash, then remove and allow it to cool off in the air.

A die should never cool off entirely in the water. When a mass of steel at the hardening temperature is plunged into cold water, the grains in its outer surface immediately become set and rigid. A certain amount of contraction and shrinkage also takes place, partly because of the change from high to a low temperature and also because of the hardening of the metal. The amount of this shrinkage is in exact proportion to the surface area of the mass being treated; the greater the area the more the shrinkage. If this change took place all the way through there would be no trouble; but it does not. In the first place, the interior of the piece cools off much more slowly than the outside, and secondly, the setting of the grains due to hardening extend in a depth of only from ¼ to ½ inch at the most. This suddenly chilled outer layer is consequently being forced against the softer mass inside with an enormous pressure, causing distortion and strains which become more marked as the piece cools off. When the temperature recedes to a certain stage, governed partly by the temperature of the quenching water and the air, a violent action takes place. This is the danger point. The friction created by the molecules striving to adjust themselves to the new conditions generates heat inside; heat means expansion, and unless this condition is offset promptly by heat applied to the outside to relieve the strains, the die, particularly if a large one, has about an even chance of bursting open. Whether it does or does not, the strains are there and are just as liable to manifest themselves in service later on as they are to appear immediately after hardening.

Allowing the dies to remain in the water too long and failure to draw the temper promptly after hardening is responsible for considerable breakage. This is partly due to the lack of proper equipment, and also to the fact that the principles involved are not so generally understood as they might be even among steel hardeners. This heat generation by friction, or as some might call it, molecular reaction inside of a body of steel, is no pet theory, but the author has noted its effects during many years of close observation and practice in the heat treating of steel. Furthermore, he believes it will be found in line with the natural laws governing cooling bodies. Be that as it may, the writer has found this method of hardening dies a success and can recommend it to steel treaters who are having trouble.

# The Proper Selection of Chain Gear

IN their book entitled "Notes on the Selection of Chain Gear," the Hans Renold of Canada, Ltd., Montreal, have the following to say regarding the erection and care of chain drives, in so far as their particular style of chain is concerned:

When erecting, watch these points:

The shafts should be horizontal and parallel. The two wheels must be in alignment. Mount all drives as close to bearings as possible. The end play of the shafts should not exceed 0.2 per cent. of the centre distance, and it is preferable to have the driving side of the chain uppermost.

Adjustment of centre distance should, if possible, be provided, more particularly for vertical drives. If the lie of the drive is from the horizontal to about 60 degrees above, it will not be necessary to adjust so frequently as the catenary pull provides a certain amount of automatic adjustment. Failing center adjustment, for vertical drives and all impulsive loads adjustable jockey sprockets should be used.

The chains of all multi-strand drives are marked on an end link with a serial number, and if more than one drive a sub-number, and also direction arrows. The joint bolts must be in line and the arrows must run in the same direction. Before and during starting up, at erection and after cleaning, lubricate freely.

### Jockeys

Never use a jockey where avoidable. Where necessary, the jockey must be a correctly cut sprocket wheel, and should have 25 teeth or over.

It should engage with the slack side of the chain, and to avoid malgearing should have at least three teeth in mesh.

Jockeys should be mounted to be adjustable, but should be locked when adjusted. Spring and weight loaded and other movable jockeys should never be used.

In the matter of maintenance, see that the chains are well lubricated. During the first two weeks after erection, this is of vital importance.

Chains should not be allowed to run too slack. When excessive slackness develops, adjust centres or jockey sprocket, otherwise take out one link of the chain. Chains should be taken down periodically and cleaned thoroughly with paraffin.

It is essential to maintain the chain free from slack in all cases where it is subject to an impulsive load, otherwise slackness permits whipping, which increases the rate of wear, and may cause malgearing. When chains become much worn it is not advisable to attempt to run them too tight. The adjustment should be made to suit, not the stationary, but the running conditions.

It is not generally advisable to run chains with an elongation of over about 3 per cent., which brings the chain out of gear with an 80-T wheel; 120 T permits of about 2 per cent. elongation.

### Lubrication

It is as important to oil the bearings (joints) of a chain as it is to oil the bearings of any other mechanism. This is evident when it is realized that the normal bearing pressures upon the wearing surfaces run from 800 pounds to 2,000 pounds per square inch.

For efficient lubrication the methods in order of merit are:

(1) To enclose the drive in a gear case, and pump a constant stream of oil on to the inside face of the chain from a filter sump.

(2) To enclose the drive in a gear case and run the chain through oil. Where the pinion is below and is too small to allow the chain to run through oil, an oil thrower disc of a larger diameter than the pinion may be mounted on the pinion shaft.

(3) By drip-feed lubricator fixed so that the oil drips regularly on to the inner face of the chain. One drip pipe should be provided for every 3 inches of chain width. A splash guard may be necessary for this method of lubrication.

(4) By wick feed. This method is useful for slow-running bush roller and block chains.

(5) In special cases the chain may be thoroughly impregnated with a suitable grease from time to time, after the periodic washings in paraffin where these are found necessary.

For all drives of over 50 h.p. and particularly for multi-strand drives, we strongly recommend pump and sump lubrication. In drives where the pinion speed is above the normal or where both wheels are small, or where the center distance is below normal, special attention must be paid to lubrication. Where there is any doubt, copious lubrication is desirable.

Drip and wick feeds to roller chains should deliver the oil between the inner and the outer side plates in order that it may penetrate to the working surface between stud and bush. The lubrication of the roller is of secondary importance. The oil used should be a medium heavy,

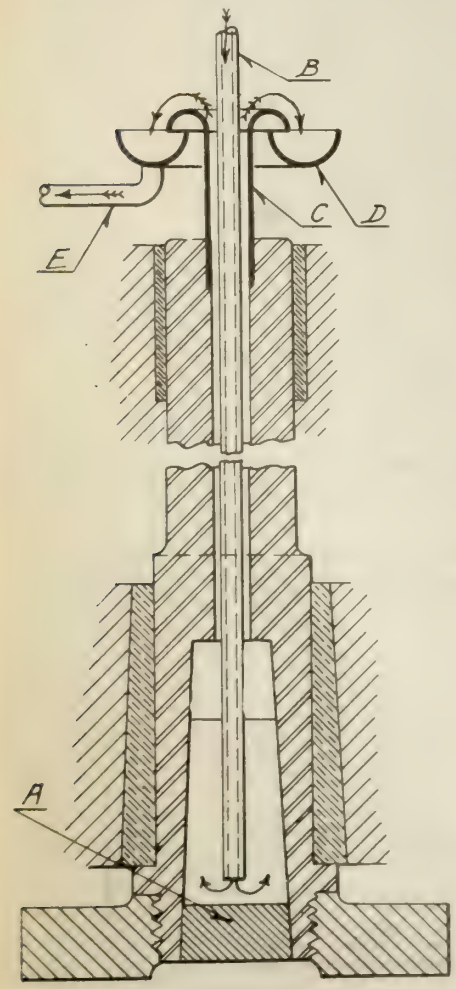
# WHAT OUR READERS THINK AND DO

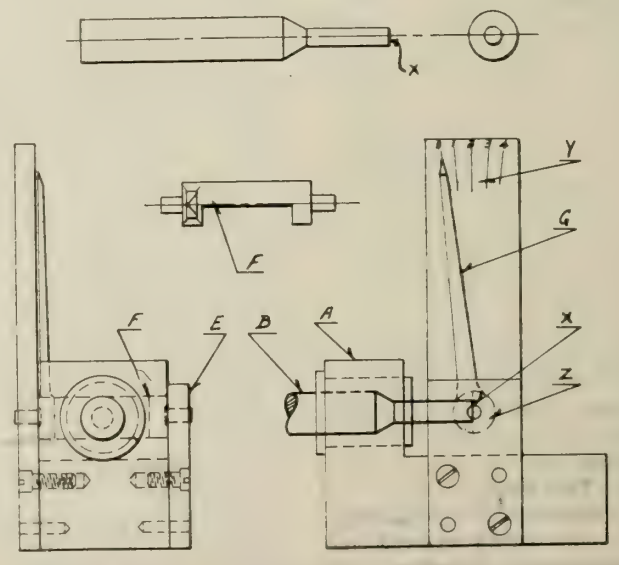


## COOLING SYSTEM FOR VERTICAL MILL

By JOHN HOMEWOOD

When continuous production is required from a vertical milling machine equipped with a revolving table, where the feed and speed are at the maximum, the lateral thrust is so excessive that in the warm months considerable trouble is experienced from overheated bearings. I am referring to that type of machine with plain bearings and a fairly good oiling system. The operation of the machine being continuous, it is almost impossible to feed oil fast enough to keep the heat away. The drawing herewith illustrates a water cooling system that assists greatly in keeping the parts in a reasonably cool condition so as to prevent seizing. Where there is only one machine in the shop of that type it is well to take every precaution so that the repair hours are kept at a minimum. This system can be used only where the spindle is free of inserted parts such as milling cutter tangs.

Where the threaded type of milling cutter is used, the lower part of the spindle can be plugged as shown at (a) and a small water pipe run down through the spindle, small enough to leave a space between the spindle and the pipe to permit the water to flow up the spindle. In the top of the spindle is a flared pipe as shown at (c) screwed into the spindle; this, of course, revolves with the spindle. Fitting underneath of this flare is a trough ring which is connected to a drain and fastened rigid. This ring is shown at (d). The pipe (b) is fastened and does not revolve.



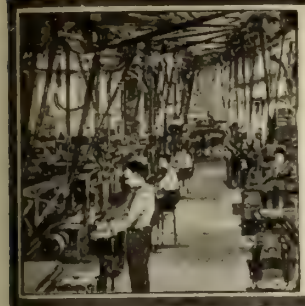
SECTIONAL VIEW THROUGH THE SPINDLE.

## LENGTH GAUGE WITH INDICATOR

By F. S.

A simple arrangement of a gauge for measuring the length from a beveled surface to the end of a part similar to that shown in Fig. 1 is illustrated at Fig. 2. This consists of a base A, containing a bushing B, while attached to base A are steel strips D and E. These steel strips provide a bearing for stud F, which contains an indicating finger G.

The object of the gauge is, that when the small diameter of the part shown in Fig. 1 is pushed in the bushing the end X will come against the rounded corner of the flat on the stud, thus pushing the indicator over, so it will be held somewhere between the indicating lines Y, provided the distance from the shoulder to the end of the work is correct. This lengths, and when reading can be taken from the indicating lines the work is, of course, correctly machined.



SHOWING WORK TO BE GAUGED, AND METHOD EMPLOYED.

## TURNING TAPERS BY SETTING OVER THE TAIL STOCK

Tapers are usually given in "inches per foot" and include the total taper or difference in diameters unless otherwise noted. In turning tapers in the lathe it is necessary to consider the total length of the bar, whether the taper extends the whole distance or not, and to set the tail stock over just as though the taper extended the whole length.

If the taper is ¾ inch per foot as in pipe threads and the whole bar is 16 inches long, then the total taper is 1 inch and the tail stock must be set over ½ inch. There is nothing to remember except to set the tail stock over half the total amount if the whole bar was tapered at the same rate.

# DEVELOPMENTS IN SHOP EQUIPMENT

### "RAPID" SAWING MACHINE

The latest design of "Rapid" sawing machine manufactured by Edward G. Herbert, Ltd., Levenshulme, Manchester, England, exemplifies the progress that has been made in the development of this type of metal cutting machine. The main features of design are strength, rigidity and an absolute minimum of working parts. The main bearings are of ample length and fitted with renewable gun metal bushes. The slide bearings are of large size, adjustable for wear and pivoted on an independent shaft with bearings wide apart. Connecting rod ends are also adjustable for wear. The saw holders are rectangular and may be adjusted to different lengths of blades and permanently aligned. The saw is set at an angle to the slides and this causes the inclination of the saw to the work to alter during the cut, and rapid cutting is obtained without the use of weights. A distinct feature of this machine is the device employed for altering the pressure on the saw blade. This is accomplished by springs in the body of the machine with a handle at the rear for changing the pressure, and dial for indicating it. By the use of a simple oil dash pot in conjunction with the angular setting of the saw and the changing speed of the crank, a positive lift is given to the saw on the return stroke. The amount of lift can be varied by controlling the flow to the dash pot piston. The dash pot also serves to prevent the saw frame from falling if a blade breaks. Each machine is fitted with an adjustable stop which automatically stops the machine at any required depth of cut. The oil pump is of the new plunger type fitted with air chamber, thus providing a large and steady supply of lubricant. These machines are built in a large variety of types and sizes to adequately handle all classes of work. Williams and Wilson, of Montreal, are Canadian distributors.

### TWIST DRILL GRINDER

The Wilmarth & Norman Co., Grand Rapids, Mich., have embodied several new features to their "Yankee" twist drill grinder. The most important of these is the adaptation of the machine for grinding drills having tapered and collared shanks, as well as those with straight shanks. The long drills having tapered or collared shanks are held as follows:

In addition to the support at the front of the drill, and at the end of the shank, it is also supported at the back end of the fluted section by a V block mounted on a round bar which extends along the holding attachment. This block may be slid along the bar to suit drills of various lengths and when a drill is too short to warrant the use of this support it can be swung out of the way.

In the case of a long straight shank drill the shank end is not supported as in the former case. When the drill is short, the V block support is swung out of the way so that it will not interfere with the tailstock. The machine is made in various sizes, nine belt driven and eight motor driven, these styles having various combinations from four holders having the following drill capacities: No. 52, to ⅝ inch, 3/32 inch to 1½ inches, ¼ inch to 2½ inches and ½ inch to 4 inches. Each style is equipped with means for obtaining different clearance angles on the work, and has a self-contained wheel-truing device.

### SPECIAL PISTON REAMER

A new type of expanding reamer, in sizes varying from ⅝ inch to 1 inch in diameter, designed particularly for the reaming of piston pin holes, is now being manufactured by the Foster-Johnson Reamer Co., of Elkhart, Ind. The cutting blades are expanded by means of an axial screw operated by a knurled head at the outer end, which is graduated for accurate setting to the thousandth part of an inch, the reaming operation being accomplished by the gradual expansion and reaming of the hole until it has attained the desired size.

## Getting The Business

ONE of the largest merchandising firms on this continent, having branches in all the principal cities of United States and Canada, has passed through the period of curtailment so far successfully, and in passing through has been gathering much information from experience.

In one of the United States branch offices it was found necessary some time ago to curtail expenses as the overhead was making the place top heavy. So it was decided to take some of the men from the sales force. This was done twice until there were only three salesmen left in the place. Finally word came, after surveying the figures from this office that it would be necessary to cut again, and two of the remaining three would have to go.

The manager of the local branch was faced with a peculiar situation. The three men were counted as good salesmen, and each of them had home and family responsibilities that could hardly be ignored. In order to let himself out and be fair to them all, he called the trio to his office, explained the whole matter, and put the proposition to them that the one showing the best month's business should be retained. They all agreed that such a chance was as fair a bargain as they could ask, and they started out on the trial.

At the end of the month the three men came in and compared figures. It was found that in each case they had piled up business larger than any month preceding it this year, and their sales were so satisfactory that none of them was let go.

That happened just a few weeks ago, and those three salesmen are at it again for another record month. They are not only saving themselves, but they are hunting up business here, there and all over that is going to be the means of keeping other men employed.

They were all of them good salesmen before, but they are better salesmen now, and they will be better still when business conditions improve. Any man who is going through the furnace now is going to come out stronger and more efficient for future business.

The experience of that firm backs up the contention that has been put forward a good many times recently, viz., that right now there is business for the man who goes out to get it. The trouble is there are too many going out with the expectation that they are not going to get anything.

## The Scrapped Battleship

THE House of Commons at Ottawa was interested in discussing prices of scrap metal last week because some vessels the government had sold for scrap had not been paid for promptly.

The chances are that when the Niobe and two submarines were sold for scrap a year or so ago, it looked like a good stroke of business because scrap prices were firm and scrap metal was much in demand.

To-day the position is different. Instead of securing $135,000 as a scrap proposition, it is doubtful if a bid could be secured at any price, unless it should be one so ridiculously low as to make certain its refusal.

It may be that the firm making the offer of $135,000 has not been able to keep pace with the decline in scrap values.

In connection with the same debate one of the members, J. Bureau, made the remark, "a good firm would not repudiate its contracts." As a bald statement this may be very true and very high-sounding, but according to actual practice, it means that Canada must have scores upon scores of very bad companies, for contracts have been cancelled wholesale by all kinds of firms during the last six months.

If the firm that contracted to take the Niobe for scrap is backing up on its contract, it is simply following a practice—a poor one, but popular—that has brought many Canadian firms into disrepute in the Old Country markets, where they still hold to the old but reasonable theory that a contract is a contract.

## Courage Is Needed

WE state it as a new axiom, and without fear of contradiction, that a man is as big as his courage.

Many a man of originality and ability has spent the years of his life in mediocre positions because of the lack of this one thing—the courage to assert himself.

Many a man of superior judgment has trailed along in the wake of someone of lesser gifts and suffered the resulting loss of his real possibilities, why?—because he has lacked faith in himself and the courage to stand up to some other person's aggressiveness, to meet him hand to hand and wrest his true leadership from some pretender.

And many and many a man has been pushed and jostled into the dull, inactive and unprofitable rearguard of life's action, has allowed himself, year after year, to wear deeper into the rut of taking things as they come, has become the disgruntled plaything of cruelly sportive circumstance, because he had not the courage to challenge fate, to seek and demand his birthright of a man's place in the world, to stand up to the punishment with which life tests out its candidates for honors.—Selected.

---

In a certain plant where gloves are furnished to workers performing certain operations, it was found that quite often one glove would be completely worn, while the other was still fit for service. These serviceable gloves were gathered, cleaned and matched. By so doing, a saving of 15 to 25 per cent. was obtained.

---

According to a recent statement, the average casting loss of five large American foundries was 9.4 per cent. In one foundry nearly 20 per cent. of the rejections when making motor-crank cases were due to cracks. In another foundry the greatest loss was due to trouble arising from sand, whilst in a third "moved cores" was the largest cause of wasters.

# MARKET DEVELOPMENTS

# The Steel Mills are Rolling at a Very Low Rate

## Pittsburgh Believes Things Are About as Low as They Can Get Now, And Any Change Must Be For the Better—Orders Coming In Are For Very Small Amounts in Nearly All Cases

TRADING has fallen off quite sharply in some sections of the iron, steel and machine tool market. Added to the general dullness of machine tool business, a number of firms are placing a quantity of used equipment on the market.

The steel market is getting along on a very small volume of business, some of the orders being for a few pounds of material. One warehouse claims that during last week they received, among other things, twenty orders for sheets, and in the lot there were just twenty sheets. It is hard to imagine a warehouse business getting down to such small limits. It is making it expensive to do business, as it takes almost as much clerical work to attend to all these small orders, while delivery charges are burdensome on these. The trade is not looking for any quick revival of buying. They have this year seen several seasonable lines go past their appointed time for starting to move out, and from this they take it they are in for a poor season right through.

Pittsburgh believes that conditions are about as low as they can get in the steel trade. The Corporation mills are still rolling a little higher than the Independents, but there is the ever-present expectation of lower prices and until this is settled one way or the other, the buyers are not going to move much.

A ten per cent. reduction in the small tool market is noted in the case of taps. Business is dull in this market and the salesmen are not adhering strictly to prices, in fact many low prices are given in order to secure the business. The buyers are still very much in control of the market and are placing their business accordingly.

The scrap metal business shows no signs of improvement. It is about as near a complete standstill as can be imagined and prospects are not bright for an improvement in the immediate future.

## PITTSBURGH PREDICTS THAT THE WORST HAS HAPPENED IN BUSINESS

Special to CANADIAN MACHINERY.

PITTSBURGH, June 2.—July is casting its shadow before. In the past few weeks the steel trade has been expecting July to be a particularly dull month, as July always is, but the particular dullness is already on the market. In other words things have gone from bad to worse, though perhaps it would be more accurate to say that the trade feels things have gone from worse to the worst. That is, the view is entertained that the worst possible conditions now exist as to demand, conditions so bad that they cannot continue. Almost universally an improvement is predicted for August, and then the question would be whether when a start was thus forced the movement would not gain momentum. It is believed that there are still some stocks in process of liquidation in the hands of some manufacturing consumers, though as to jobbers' stocks it is thought they were quite well liquidated several weeks ago. If there is consumption of stock at the present time then there will be heavier demand on mills when these stocks are completely exhausted, provided the consumption continues. In most cases it doubtless would. In the automobile industry there is a question. It is well known that even to-day a very considerable part of the automobile consumption of steel is of stocks which presumably will very soon be almost entirely exhausted, but with automobiles there is the question whether manufacturing will be continued on anything like the present scale, now that the natural spring demand is fairly well filled. Some steel manufacturers believe that certain automobile manufacturers will make sweeping price reductions not long after July 1, and these may start some fresh buying.

### Economic Conditions

In his address last Friday as president of the American Iron and Steel Institute, Judge Gary, chairman of the Steel Corporation, set forth in his usual lucid style, and in the stronger language he has lately used, in discussing the extortion attempted by some sellers of commodities and some groups of workmen, the economic situation as it has lately been generally understood in the steel trade. Prices of some commodities are all right, or nearly all right, while some prices are "unreasonable and unfair, if not extortionate" and much the same is true of some wage rates. Judge Gary says the whole public is holding back from buying, when the means and the inclination exist, because the public feels that a general readjustment is necessary and the readjustment has not been completed. Thus there are some "spoilsports" who are holding back business revival.

Judge Gary seems to hold the opinion that the buying public is holding back its buying power merely from a general disinclination to do anything or make any purchases because it holds that further readjustment is necessary. Perhaps, however, in many cases the buyer's hands are tied because to do a certain thing he needs two or more commodities, and cannot use one without the others, while one of the commodities may be rightly priced and the other unreasonably priced.

The steel trade's view of the future is definite and plainly expressed. It expects some revival in demand in August or soon thereafter, no matter what happens, because even the smallest kind of hard times consumption that can be conceived will in the long run require more steel than is now being purchased or specified for against contracts, and that a fuller revival in steel demand, which hinges upon adjustment of the general economic situation will come later, and not until next year. That adjustment involves the development of fair prices

for all commodities and fair wage rates for all classes of service.

### Operations

It seems quite certain that the steel ingot report for May, when issued, will show an operating rate for the month under 30 per cent., against about 31 per cent. for April, 55 per cent. for January and 80 per cent. for the first nine months of last year, before shortage of orders was felt, but while there was restriction by transportation and other conditions. The average in June and July is likely to be 25 per cent. or less. The Steel Corporation continues to operate at a considerably better rate than the independents, due to its having increased its good will last year by holding down its prices, while it still has large contracts on which customers specify as they need material.

### Prices

In almost every branch the steel market is quite steady at the prices developed about the middle of April. This steadiness may or may not be an actual evidence of inherent strength. There is no real test because the quantities sought by buyers are not of sufficient size individually to tempt a seller to cut regular prices, even though he might be disposed to do so on a good sized order. Another factor is that buyers are making purchases in such extremely hand-to-mouth manner that they hardly have time to shop around. Frequently the order is simply placed with the mill that can make the quickest shipment. This interferes with the policy often practised in dull times, of a mill closing for a time "to accumulate orders." Often if a mill is not going to operate until next week it does not get the order just on that account, and in such circumstances it is obviously difficult to "accumulate" orders.

It is regarded as practically a foregone conclusion that steel prices will be lower before there is anything like a general buying movement. Buyers evidently expect this, while mills would not be averse to lowering prices if they were in line to receive more business and thus be able to operate at a higher rate, thus reducing their costs. With the present very light operation many mills have no profits even at present prices.

### Pig Iron

Pig iron continues, in general, its established practice of yielding a little in price whenever any new business of the least consequence comes out. Basic iron recently declined from $22.50, valley to $22 on a 2,000-ton lot, a few small lots afterwards changing hands at the $22 price, while now on purchases of 2,000 tons $21.75 has been done and it is rumored that the sales were followed by one transaction at $21.50. In somewhat similar manner foundry iron has declined from $23.50 to $23.

Connellsville coke for spot or prompt shipment remains quotable at $3.25 to $3.50 for furnace and at $5 to $5.50 for foundry, per net ton, at ovens. It is understood that on a contract for a furnace supply for about four months $3.75 has just been done, this being on a particularly good grade of coke for making low phosphorus pig iron, the reported buyer being the Robesonia Iron Company.

## POINTS IN WEEK'S MARKETING NOTES

**July bookings are very low in the steel mills, and many of the mills hold that conditions have reached a point as low as it is possible to go.**

—

**Many of the automobile shops have been running on stocks that the firms had on hand some months ago. Now that the spring demand has been attended to, the manufacturing programmes have been seriously curtailed.**

—

**Toronto warehouses are selling in very small quantities, some orders coming in for as low as a few pounds of material.**

—

**Prices of taps have been reduced ten per cent. Dealers admit that considerable price shading is being done in small tools generally in an effort to secure business.**

—

**A few orders for boiler tubes have come in during the week.**

—

**It is freely predicted that automobile prices are going to be cut after July 1, and that some of the cuts may be quite heavy. This may cause fresh buying of steel.**

—

**The Steel Corporation mills continue to operate at a higher rate than the Independents.**

—

**Our Pittsburg correspondent claims, "It is regarded as practically a foregone conclusion that steel prices will be lower before there is anything like a general buying movement."**

—

**Pig iron has touched a new low spot, as some sales as high as 2,000 tons have been done at $21.75.**

## TORONTO HAS A QUIET MARKET

**Machine Tool Dealers Are Receiving Very Few Orders—Steel Dealers Order in Small Lumps**

TORONTO.—There have been a few bright spots in the iron, steel and machine tool markets during the past week, but they are few and rather far between. One of the hardest problems facing many of the firms is to handle profitably the same number of orders representing only a quarter of the usual volume of business. It requires the same amount of clerical work, the same trouble in delivering and the expenses generally are greater in doing business this way.

The machine tool market remains dull, and sales are limited to a single machine here and there, and, as further indicating the tendency of the buying, a used tool at a close price seems to be the easiest to dispose of in the present market. Several firms are letting out quite a lot of equipment at the present time, and this may be having the effect of further depressing the market, although it is doubtful if the sales of new machines are interfered with by this practice.

A number of the machine tool houses are cutting their expenses as closely as possible, trying to keep them in line with the volume of business that is offering. There is a tendency, though, to keep organizations pretty well built up, for, despite the quiet trade, there is a feeling that business is going to improve, and firms want to be in good shape to follow up all the leads showing when the turn of the tide comes.

### The Small Tool Market

Small tools have been fair during the last few weeks. There is a new price out on taps this week which really amounts to a reduction of about 10 per cent. Tehere seems to be a tendency to shade prices on quite a few lines in small tools. For instance, files are listed at 50 off. One dealer found a firm ready to place some business, and in order to make sure of grabbing it he offered 60 off. To his surprise he received word that the buyer—or rather prospective buyer—could do quite a bit better than that. Speaking to this paper the dealer said, "My price on that line is 60 and 10 off, and there was not much left for me when I offered to make the price 60 off. The order must have been taken with no profit at all. The trouble is that when buyers find out they can get such treatment they want it on everything they secure, and when it is necessary to get back to real business, it is hard to convince them that they are not in control of the market any more."

Several dealers claimed that there was considerable shading of prices going on in order to secure business. The odd part of it is that some of those who complain of this sort of business will admit that they themselves are guilty of it. The automobile shops were buying a little a few weeks ago, but they have not come into the market very prominently as buyers of small tools. In fact some of the auto shops were so heavily stocked up a year ago that they can turn around and sell quite an assortment of material to the average dealer, and still

have enough material on hand to go ahead and run the establishment.

### Small Orders For Steel

The steel merchants are getting business handed to them in about as small quantities as could be imagined. Buying from hand to mouth hardly expresses the size of some of the orders that are drifting in to the warehouses just now. It is quite correct to say that these orders are coming in, for it certainly would not pay any steel merchant to go out and seek them. A couple of weeks ago we recounted the case of a firm that sent out a three-ton truck with 47 orders on it, but this week we hear of another that had orders for twenty sheets for twenty people, or one sheet to a customer. The warehouses are talking of coming to some understanding as to what amount they will deliver without making a special charge for handling. Some of them seem to think that 100 pounds should be the limit, and that anything under that should be charged specially for delivery service. There are many orders for lesser amounts, one merchant showing Canadian Machinery a filled out order for some quarter round bars that would weigh between eight and ten pounds.

There have been a few fairly nice orders for boiler tubes, but not many of them. Other lines are moving very slowly, and dealers are not looking for any speedy revival of their business, as several seasonable lines have failed to move at their expected time.

### No Change Here

"You can say there is no change whatever in the scrap metal situation," explained one dealer this week. "The amount of business that is moving is very small, and is only such as some person is anxious to secure for immediate use. Scrap must be piling up in the premises of some of the firms that usually have a pretty fair offering for the market. Very little of it is offered for sale, because the prices are so low that they would rather hold on and see if there will not be something better later on. We are studying the situation closely from day to day, and we cannot find any sign that would lead us to believe we are soon to face any decided improvement in our business."

## REPORTS FROM ONTARIO CENTRES

**How the Bankers Report Conditions In Various Corners of This Province**

A number of reports have been received at the head office of the Imperial Bank regarding conditions in the various centres of the province. A review of some of these shows the following statements:

**Hamilton.**—Generally speaking, the manufacturers of this district are running half-time or less. Two exceptions are the Canadian Westinghouse and the National Steel Car, which are running full time, and working on large orders. Unemployment is about 4 per cent. of the working men of the city, and, as 1 per cent. is the average rate of men out of employment, the situation does not appear to be very serious.

**St. Catharines.**—Steel manufacturers are all working on short time, none of them more than four days a week, and their orders are light. Paper mills seem to be better off than the other manufacturing concerns, and have a lot of orders, but they are not as large as in former years. Customers are buying in small lots and oftener.

**Welland.**—Factories are closed or on short time as a rule. There is quite a number of unemployed, and until their savings are exhausted they appear to be unwilling to go to work on the land.

**Niagara-on-the-Lake.**—Our fishermen have nearly all been obliged to go over to the north shore of Lake Ontario, owing to the state of the lake at the entrance to the Niagara River.

**Niagara Falls.**—Local manufacturers are looking for gradual improvement. Some concerns are operating full time, while others are 50 per cent. of capacity.

**Port Colborne.**—International Nickel Co. is operating 25 per cent. of capacity, and has sufficient nickel to supply a normal year's demand. They are shipping 100 tons a month to Japan, and this order will be completed in June. A resume of the situation would indicate that this town will not suffer to any great extent by the prevailing general depression throughout the country.

**Brantford.**—Some of our manufacturing concerns show an improvement, but, generally speaking, all are running from 50 to 75 per cent. below capacity.

**Galt.**—With the exception of heavy machinery and winter weight textiles, practically all lines of manufacturing show an improvement over the first of the year. The number of orders is back almost to normal, but the size of the orders is very small, and in many cases express shipments are made where carload lots were formerly the rule. This condition indicates a lack of confidence in the stability of present prices, and this lack of confidence cannot but continue until there is a marked reduction in present costs. "The well-meant effort of some municipalities to create work at top prices for the unemployed seems to me to be an unsound policy, which is only postponing the inevitable readjustment into the winter months, when the pinch will be much harder than it is today."

**Woodstock, Ont.**—Knitting and textile factories have been very busy generally and report that orders are coming in freely. The outlook for the next few months is for a gradual improvement.

**Windsor, Ont.**—Mostly all lines of manufacturing are running on short hours with reduced staffs. There has been a vast falling off in business in general throughout Ontario during the past several months, and the same condition prevails here, but I do not believe to as great an extent so far as in some other sections.

## SITUATION BETTER AROUND REGINA

**Imperial Oil Refining Plant is Being Enlarged—Much Residential Building Being Done**

Writing to Canadian Machinery, Charles A. Cooke, secretary-manager of the Regina Board of Trade, says:—

Industrial construction in Regina is somewhat less active than usual, though building permits to date are in excess of the same period in 1920. The great proportion of the work, however, consists of residential property.

Considerable extension is planned by Imperial Oil Limited at their refining plant, and the contract has been awarded for the erection of a large distribution warehouse for McColl Bros. who have established a branch of their oil business here.

Construction will begin at an early date on the new Campion College to be erected by the Roman Catholic community.

A large number of houses are under construction, many of them more than ordinarily costly, but high costs are militating against much needed development along residential lines.

Both wholesalers and retailers report fair conditions generally, and the optimistic reports on seeding operations and crop possibilities are tending to an easier situation.

## GOING TO GIVE THE RETURNS MONTHLY

**Production of Pig Iron In Canada Had Fallen Off Sharply During January**

With seven out of 20 blast furnaces that are installed operating in Canada during January of this year, the total production of pig iron, exclusive of ferro-alloys, was 41,249 long tons, the lowest since 1904, reports the Dominion Bureau of Statistics. Of this amount 28,326 tons were made for the use of firms producing, and the remainder was for sale. All iron produced by firms for their own use was basic; of the remainder, 137 tons were basic; 3,027 foundry, and 9,759 malleable. The furnaces were operated at Sault Ste. Marie, Midland, Port Colborne and Sydney, C. B.

This decline in production was reflected in the steel industry, the output of steel ingots and castings in January amounting to 40,058 long tons, the lowest since 1904. Only 371 tons were for sale.

The Dominion Bureau of Statistics will

produce these figures monthly. Figures for February, March and April will be issued shortly. These returns will be in continuation of the service formerly provided by the mines branch of the Department of Mines. A few changes have been made, notably the reporting on a monthly basis instead of quarterly, the record of pig iron production by grades, and the showing of all quantities in gross tons of 2,240 pounds, whereas formerly the figures of pig iron and steel production were always given in short tons.

# OTTAWA HOUSE DISCUSSES DROP IN SCRAP AND NIOBE CONTRACT

OTTAWA.—Scrap iron prices and Canada's naval policy got all mixed up in the debate on naval estimates in the House.

The scrap iron prices came in the discussion on the sale by the Government of the warships Rainbow and Niobe, and the two submarines. The Niobe cost Canada $1,200,000. She sold by tender for $135,000 along with the two submarines, but the Federal Treasury is only the richer by $10,000. The two submarines included in the same deal, about which there is difficulty now in getting the money, cost Canada $1,500,000. The failure of Hon. C. C. Ballantyne to get the money required about an hour of explanation. The net result of it is that the House was informed that the Department of Justice has the matter in hand, and will try and force the New Brunswick rolling mills, purchasers of the Niobe, to keep the full terms of contract of sale.

### Not Carrying Out Terms

The Niobe was sold last December, and besides the $20,000 paid then, the firm was to pay $10,000 a month. The latter stipulation has not been lived up to by the firm. It was the opinion of the Minister and others that, because of declining prices of steel and brass, the firm, which has already taken the two submarines, is trying to get out of the contract of taking the Niobe.

A. E. Fripp, one of the Government members from Ottawa, sought an explanation of tenders. He stated that an Ottawa firm had tendered for $100,000 cash. He maintained that if they had known the arrangements made with the New Brunswick firm that they would have bid higher and paid cash, which would be a better deal than the present one. He was critical of the whole transaction and wanted to know what security the Government had from the purchasers of the ships.

Mr. Ballantyne explained that the ship itself was the security, whereupon Mr. Bureau remarked that he could not get $20,000 for it now, in view of the declining prices of iron and steel. The Minister persisted that the firm was in a position to pay, and that the Government would insist upon them living up to the contract.

# FIRM IN INDIA IS ANXIOUS TO HAVE TRADE RELATIONS WITH CANADA

Canadian Machinery has received from Lala, Ramdhan & Sons, engineers and contractors, Jullundur City, India, the following list. The firm is anxious to get in touch with Canadian manufacturers who can supply the lines indicated.

Ice making plants—For 20 tons per day, clear and crystal. The temperature of water on hot days is 85 degrees Fahrenheit, and depth of well to be built is 35 feet. Ice blocks to be 3½ ft. x 2½ ft. x 8 in., and 336 pounds in weight. Require complete estimate with cost of boiler and all accessories, including electrical light apparatus.

Steel and iron products—Round, flat and square bars, angles and rolled bars of all sizes, pipes, tubes and bends for water works, plain, corrugated and galvanized sheets, tin plates, wire gauges and wire of all descriptions, bolts, nuts, screws and wire nails, door fittings, scales, weighing machines and other building materials, zinc and lead. Also tools for carpenters, engineers, etc.

Brass and copper products—Sheets of all sizes, door fittings, screws, tubes, locks, cocks, wires and wire gauges.

The quotations may be given f.o.b. Karachi, otherwise the shipment and other charges up to Karachi may be shown separately. State time of delivery from the receipt of orders and the method of payment. In the case of suitable rates we will be prepared to pay 25 per cent., with order and remainder as desired.

We are prepared to take the agency for India for manufacturers who have no representatives in this country. Send samples if possible and full price lists. Our banking references: The Punjab National Bank, Ltd., Lahore; the Alliance Bank of Simla, Ltd., Jullundur; the Lyallpur Bank, Ltd., Bannu. Correspondence can be carried on in the English language.

---

**Start Operations.**—The Bluebird Corporation, Brantford, expect to resume operations about the 1st of June, after being closed down for some weeks. In addition to manufacturing the Bluebird washer they will make a new line of electrical appliances.

# ENGLISH ELECTRIC COMING TO CANADA

### Toronto Man to Look After Establishment of Lang Electrical Concern In This Country

Gordon Foxbar Perry, president and general manager of the National Iron Corporation, Limited, Toronto, has been elected president and chairman of the board of directors of the English Electric Company, Limited, a Canadian company incorporated with a Dominion charter to handle the business in this country of the English Electric Company, Limited, of London, England. Mr. Perry was born on November 28, 1883, in Dundas, Ont., and was educated in Toronto. After serving four years' apprenticeship in the foundry and machine shop of the Canada Foundry Company, Limited, now Canadian Allis-Chalmers, Limited, Toronto, Mr. Perry became a salesman for that firm in 1904, and two years later he was promoted to be Ontario sales manager. In 1910 Mr. Perry resigned this position to become general manager of the newly incorporated National Iron Works, Limited, which subsequently became the National Iron Corporation, Limited. Working jointly with the late Cawthra Mulock, Mr. Perry successfully established the modern foundry in the Eastern Harbor Terminal District, Toronto, for the manufacture of cast-iron water and gas pipe, and upon Mr. Mulock's death he succeeded to the presidency of the company. Mr. Perry is vice-president of the National Steamship Company, vice-president, Eastern Construction Company; director, O'Keefe Brewing Company; vice-president of the newly incorporated Drifting Sand Filter Company, Limited, and a director of several other companies. Mr. Perry is also a director of the International De Lavaud Manufacturing Corporation, a company that has been organized to control the patents for the De Lavaud process for casting iron pipe by centrifugal force. He has been been in England for the past three months in connection with the organization of the Canadian subsidiary for the English Electric Company, and on business in connection with the European patents for the De Lavaud process.

---

Car Owners Garage Co., Richmond and Maple Sts., London, Ont., will remodel building for garage at Aylmer, Ont.

The general contract for the erection of a warehouse for Bonsall and Mitchell, Coronation, Alta., has been awarded to Ed. Bartlett, Coronation.

The Robin Hood Service Stations, Ltd., 502 Ryrie Building, Toronto, are contemplating the erection of a service station at a cost of $15,000 at Oshawa, Ont.

The Sandwich Foundry Ltd., Sandwich, Ont., has been incorporated with capital stock of $200,000 to carry on business as iron, brass and aluminum

# Serious Problems in the Old Country Centres

## Reductions Have Been Made in a Number of Lines, But Foreign Competition is Still Able to Make Itself Felt—Present Coal Strike is Delaying Progress Very Seriously in All Lines

LONDON, England.—The future of the iron and steel trade in Great Britain is so closely interwoven with the British coal situation that it is impossible to dissociate the two. It is certain that there can be no general or marked improvement in the iron and steel trade until coal is cheaper. Coal miners and operators equally appreciate the importance of this situation. Only recently, Mr. Hodges, secretary of the Miners' Federation, made the statement that a reduction in the price of industrial coal of £1 per ton would mean a reduction in the cost of production of pig iron of £4 per ton, a reduction which in view of foreign competition, is essential to the iron and steel trade if it is to maintain not only its foreign markets but its domestic as well.

For some time it has been realized that British pig iron prices are far too high to maintain a reasonable volume of domestic business as well as export trade, in view of the keen competition from Belgium and Germany. It was felt by the various interests associated that a gradual decline in prices of British pig iron would only serve to confirm the mind of the buyer to delay purchasing in anticipation of further reductions. Therefore it was decided on the part of the producers of Cleveland forge iron to reduce prices on March 1 by a slashing cut of 45s. a ton. This step was taken only after careful consideration, in the expectation, first, that coal and coke prices would soon be lower and, second, that such a drastic reduction would stimulate buying. Nevertheless, in taking this step many of the producers of Cleveland pig iron are obliged to shoulder heavy losses based on production cost until coal and coke are cheaper or orders increase to such an extent as will give them a large volume of trade on a small margin of profit.

### Result of Decline in Price of Cleveland Iron

Cleveland pig iron is now quoted at the following nominal prices: No. 1 foundry, £7 15s. per ton (at normal exchange the pound sterling is equivalent to $4.8665, the shilling to $0.243); No. 2 silicious, £7 15s. per ton; No. 3, G. M. B., £7 10s. per ton, with lower grades correspondingly cheaper. In spite of this extreme and sudden reduction, Belgian foundry iron still undersells it, being obtainable c. i. f. Tyneside at £7 10s. per ton, and an excellent grade of foundry iron offered through Belgium, equivalent in quality to No. 3, Cleveland, at £6 10s. per ton f. o. b. Tyneside. It is genrally believed that this iron was smelted in Germany, hence the great difference in price.

The first and most important result of the lowering of prices was the effect on the producers of hematite iron. The reduction came as a bombshell in this field, and equivalent hematite declined in sympathy 40s. per ton, Cumberland hematite 20s., and Scotch hematite 20s. per ton. This left the market for hematite in a demoralized condition, from which it has not yet recovered. The anticipated new business resulting from the reduction in the price of Cleveland and hematite iron has not yet been realized, and such improvement as is noted is sporadic and scant. British makers point to the fact, however, that continental pig iron producers are fairly well sold ahead, and this leads to the view that there must be in the near future at least a moderate resumption of domestic buying of pig iron in view of the lower prices.

### The Manufactured Iron Situation

The manufactured iron situation throughout the country remains unchanged. If anything, there is a slight falling off in business. Old contracts are being rapidly completed and the tonnage of new orders is far from keeping the volume of business on hand up to a normal figure. The opinion is generally expressed that the finished iron and steel trade has never gone through a period of more complete stagnation. Fresh orders for finished iron are lacking in all branches of production, with a possible exception in connection with marked bars; but here, while makers were well booked at the beginning of the depression, the contracts are being finished off much more quickly than new ones are coming forward. A strange feature of the situation is the fact that finished iron is being displaced by cheaper continental steel where it can be suitably used.

As a result of this, many of the producers of finished iron have been cutting the association price to a substantial extent, provided this would bring them additional business, but in most cases it has proved of little avail. The associated makers, realizing this, have recently reduced their prices £2 per ton for both crown and marked bars. The hopes of an early spring revival in the finished iron trade have not materialized. Certainly if there is to be any improvement this side of fall, it must begin very soon.

In the Scottish district makers of bar iron reduced the price of this commodity to £23 per ton, and are reducing the extras to 100 per cent. over the list prices. Here, too, business is getting quieter each week, and most producers are operating on short time.

### Foreign Competition in Manufactured Steel

In manufactured steel any hope of immediate improvement is overshadowed by foreign competition. Particularly is this true in semi-finished steel. In fact, it is difficult to keep pace with the slump in prices of imported semi-finish. For instance, a great deal of attention was attracted two weeks ago to the fact that Belgian steel bars could be bought at a price which was slightly less than £10 per ton delivered in South Staffordshire, the center of the steel-bar industry, but at the present time Belgian bars are being offered at slightly less than £9 per ton. It is not strange, in view of this fact, that British manufacturers find it impossible and impracticable to book orders for steel from domestic producers.

The reduction in the price of steel sections made last week has done nothing to stimulate domestic trade, and the general feeling is that there must be further and heavier reductions in all lines of steel before bedrock is reached. Scottish steel producers are feeling Belgian and German competition very keenly, and steelmakers generally are finding difficulty in getting orders of sufficient tonnage to make up rollings. The drop in sheet-steel prices has done little to stimulate the trade, and as a result a further slump is anticipated within the next few days.

### Exports of Manufactured Iron and Steel

The most serious phase of the situation is disclosed by the tonnage figures available showing shipments of pig iron and manufactured iron and steel from the Middlesboro district for February, 1921, as compared with January, 1921. January showed considerable strength as far as exports of manufactured iron and steel were concerned, but this was not surprising when one reflects that the shipment represented deliveries on contracts placed during the height of the boom period. Shipments of manufactured iron and steel by water amounted in January, 1921, to 32,900 tons. These shipments fell in February to 21,646 tons. Of this total of 21,646 tons, 333 tons went coastwise and the balance abroad.

It is particularly interesting to note how badly the iron and steel trades have been hit in the Ceylon and Indian markets during the month, probably due to a large extent to the depression in silver. In January, 1921, 15,249 tons of manufactured iron and steel went to India and Ceylon, while in February only 6,959 tons were shipped. The aggregate shipments of pig iron and manu-

actured iron and steel during February om the Middlesboro district amounted 34,447 tons, as against 44,688 tons in anuary.

In view of the general economic and dustrial situation, and in particular to he great uncertainty of the result of he present coal crisis, it is difficult to nd substantial evidence of any lasting or appreciable change for the better in the British iron and steel situation before next autumn. In the event, however, that the coal crisis should develop into a severe and long drawn out struggle, we may see the resumption of normal conditions in the iron and steel trade delayed a much longer period.

# PLANNING TO MAKE USE OF THE IRON ORE DEPOSITS OF CANADA

N view of the heavy imports of iron ore into Canada and the relatively mall use being made of the native eposits, the question of developing the ater on a large commercial scale is tracting increased attention. The ques- on has been taken up energetically by he Ontario Mining Association, and hile the solution of the matter has not et been reached, emphasis is placed on he results of recent experiments in reating what is considered to be sim- ar ore in the Western States. It has een suggested that a bonus be granted y the Government to encourage this ndustry, but it is not certain that this s the only or best method of achieving he result. Research is apparently ecessary, and it is contended that pri- ate enterprise would solve the matter vith reasonable Government support. One advocate of action took the ground hat a small bonus from the Government would put the industry over the hill, and make available Canadian iron at a cost no greater than American ore, allowing for the exchange which must be paid on imports from that country. This argument, he considered, was all the stronger because of the probability that exchange will be a relatively high addition to cost of imports from the United States for an indefinite time to come.

### Possibilities of Industry

It is pointed out by the Ontario Mining Association that the annual output of pig-iron in the United States has a greater value than any other single manufactured product, and greater also than all other metals combined. Starting with practically nothing at the beginning of last century, the production has increased at an average rate of 100 per cent. each decade until it is now the most important single industry in the United States, with an output of 40,000,000 tons of pig-iron per year, and furnishing, approximately, one-fifth of the total tonnage handled by the United States railways. It is maintained that a great steel industry has been built up in Canada, with an average production of about 1,000,000 tons of pig-iron per year, largely by reason of the bounty paid for a number of years on pig-iron produced in this country. Unfortunately, however, year by year the proportion of domestic iron ore used in Canada's present production of pig-iron has grown less and less, and at the present time not one ton of iron ore is supplied from Canadian mines. It is estimated that Canada has iron ore resources posi ively proven to the extent of well over 500,000,000 tons, and a smelter capacity of, approximately, 2,000,000 tons of pig-iron per year, and yet the country is at present importing every pound of iron ore smelted in Canada.

### Results in U. S. Experiments

Already, in the United States, preparations are being made for the time when the high-grade iron deposits will be exhausted, and important studies of the treatment of other deposits are under way. An immense plant costing $3,000,000 has been almost completed by Hayden, Stone & Co., at Babbit, Wis., after exhaustive experiments at West Duluth for the purpose of beneficiating taconite or low-grade iron ore deposits. Ore running from 32 to 38 per cent. is

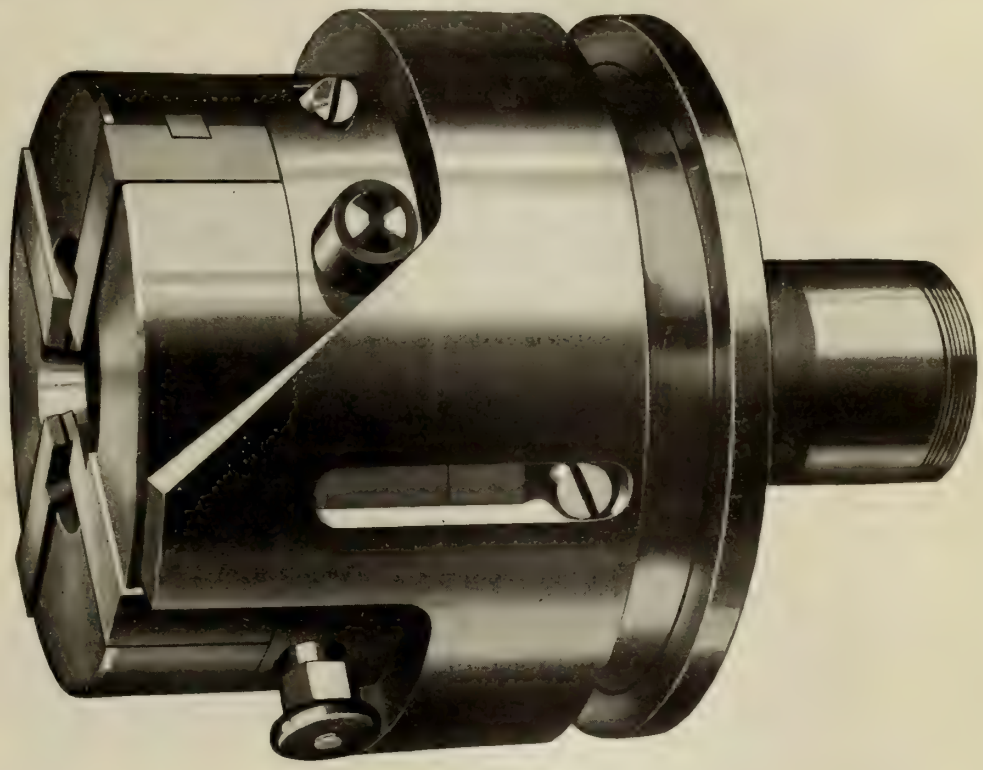
# Ordered By The Million



That's the way Studs for Automobiles are ordered from the Chapman Service Company. An order for one million Studs at one time is no novelty to these people, who specialize on Automobile Studs.

## They Have To Get Quick Production Without Waste

***How Do They Do It?***

Geometric 9-16-inch Rotary Die Heads are the means they use for cutting ½-inch diameter, 20-pitch thread on alloy steel studs.

**A Geometric Rotary Die Head Self-Opening and Adjustable**

Tested for accuracy, there were only nine rejections out of 4,500 Studs, threaded at both ends.

WELL, THEY ARE GEOMETRIC DIE HEADS—
THAT TELLS THE STORY OF THEIR WORTH.

concentrated to 60 per cent., or better. It is claimed that the result of these experiments would justify action on the lower-grade Canadian iron ores, with a view to securing use of the home product at a great saving to the country as a whole. It is pointed out that Canada is wealthy in water-powers, and that the success in developing other mineral deposits would justify entering earnestly upon the solution of the iron problem.

# THE MAN WHO WANTS BUSINESS MUST FIGHT FOR IT THIS SEASON

Lloyd Harris, former trade commissioner, paid his respects to government methods of conducting business, and also to the way that business was to be secured, in a recent address in Toronto.

"The government is so inefficient that it has less business understanding and tact than the boy in the street," declared Mr. Harris. "Wherever there is a business in good shape it withers immediately when the government meddles with it," he said.

"We knew this depression was coming, we hoped against hope that it would not come, and now it is here," he said, "and the best thing is to face it, and to take drastic steps to overcome it. To that end it is necessary that in the period of readjustment all will accept their losses.

"We know that one of the worst things the government could do was to impose the business profits tax," said Mr. Harris. "There is nothing like this vicious tax which helped to bring about present conditions.

"I am not looking for any great revival within a month or two. I think that next spring will be the time when things start to pick up. In the meantime we should get our houses in order and our organizations in shape, if we want to start in on a sound basis when business goes back to its former prosperity," the speaker declared.

### Must Fight For Business

"During the coming months you men who go out for orders will not have them handed to you on silver platters—you will have to fight for your orders," he said. "I cannot see any great reduction in the cost of living yet," the speaker continued. "The cause of it is that our distribution system is all wrong. Our retailers and labor will have to do their share in accepting the losses which this period of reconstruction necessarily brings along with it," he said.

"The labor situation is a serious obstacle in the way to bring things back to a normal basis," he said.

"One thing that would help the situation in rapidly returning to normal conditions would be the harvesting of a bumper crop in the West this year, as in 1915," Mr. Harris thought. "The Canadian West is in a bad shape today," continued the speaker. "Prices were the lowest paid for years; many of the farmers had to borrow money, and got behind. A bumper crop will save us."

---

**Has the Agency.**—R. S. Griffith, 371 St. James St., Montreal, has obtained the Canadian selling rights for Vickers Limited, of London, England, manufacturers and distributors of Vickers-Petter oil engines for marine and stationary purposes, in sizes from 10 to 450 B.H.P. Other lines handled will be the Moler sound-proof building bricks made by the associated firm of Moler Fireproof Brick and Partition Company. Another line will be that of Vickers files made at the River Don Works at Sheffield.

### THE END OF THE CHASE

**It cost a lot of money to bag that rabbit.**

—Collier's Weekly.

## Trade Gossip

**The Ontario Flax Mills**, Exeter, Ont., were destroyed by fire recently.

**Ontario Flax Mills** are likely to build a factory at Exeter, which will cost at least $10,000.

**Wants a Drill.**—W. H. Mortimer of Walkerton, Ont., is in the market for a drilling machine.

**Fire damaged** the premises of the Chew Lumber Company at Vancouver to the extent of $25,000.

**The Prairie Cold Storage** Company, of Winnipeg, are planning to erect a branch plant at Dauphin, Man.

**Want Engineer.**—Oshawa is advertising for a town engineer. F. E. Hare is the town clerk, and applications should be sent in at once.

**The Sydney Foundry & Machine** Works, Ltd., Pitt Street, Sydney, N. S., are constructing docks and warehouses at a cost of $60,000.

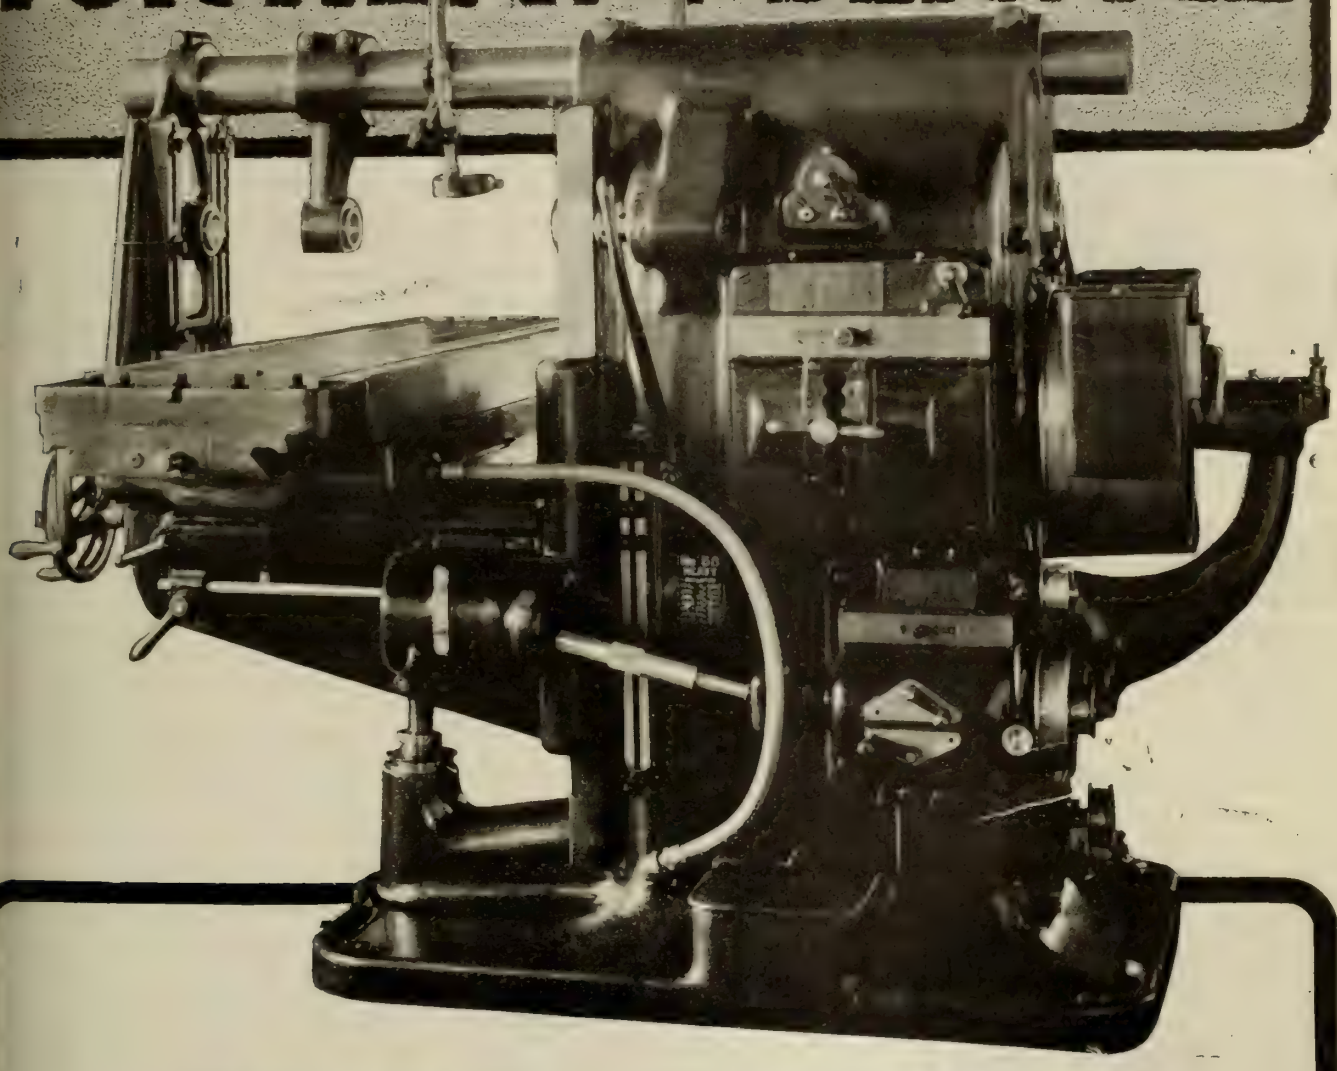
**Wants Equipment.**—Edgar B. Rolston, Kerrobert, Sask., wants to purchase a small sawmill outfit and planer, also water wheel equipment.

**The woolen mill** of Brown and Wigle, which was destroyed at Kingsville some time ago, will be rebuilt. The cost is estimated as being close to $40,000.

**Cut Coal Rates.**—The Board of Railway Commissioners have cut the rate on coal moving in the Canadian West ten per cent., the time limit to be from June 1 to August 21.

**Build Machine Shop.** — The erection of a machine shop is under consideration by Warren Bros., 314 Talbot Street London. The cost is likely to be in the neighborhood of $25,000.

**J. E. Tremayne**, of the city architect' department, Toronto, has been appointed as engineer to succeed E. R. Grang who resigned recently to take a positio as inspector of qualifications with th Air Board, Ottawa.



**Enlarge Station.**—The town of Antig onish, N.S., will probably construct pumping station at a cost of about $15 000. Other improvements are also unde consideration, including the enlargemer of the reservoir.

**Building Mill.**—A large pulp mill is t be a reality on the shore of Lake Tim iskaming, at a point about two or thre miles north from Haileybury. A forc of men has been engaged and is alread at work excavating for the foundation

**Roy W. MacKeen** has been appointe general sales agent of the Dominic Iron and Steel Co., Ltd., succeeding th late P. G. McNaughton. Mr. MacKee has been with the company for 21 year and until recently he was assistant ge eral sales agent at Montreal.

**Selling Machinery**—A number of dea ers and others have been at the pla of Armstrong-Whitworth at Longueu

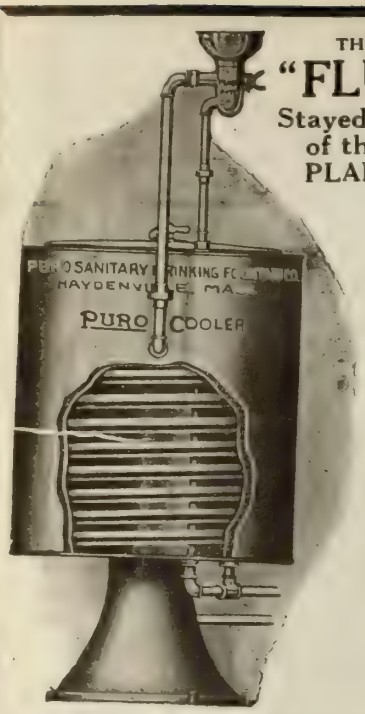
are massively built but well proportioned. The strongly braced column with thick walls and internal supports is cast solid with the bare base providing a firm foundation for these rugged machines. The extra thick front wall and rigidly designed knee with its liberal extension of bearing at the top—the point of greatest stress—successfully resist all stresses that might tend to produce vibration. Accurate milling on the heaviest work that comes within range of a column and knee machine is thus assured. The powerful drive with efficient speed and feed changing mechanism, handy arrangement of all operating levers, handwheels, etc., permit quick setting up and rapid operation.



***Send for our Milling Machine Book describing these machines in detail.***

where they are selling their equipment. Some fairly large purchases have been made already, a portion of the buying being done by dealers from Toronto and district.

**Company Appeals.**—Emile Belanger, 26 years of age, who lost both his arms as a result of an accident while operating a machine belonging to the Consolidated Rubber Company at Montreal, has been awarded $17,500 by a judgment of the Superior Court, to compensate him for his loss. The company is appealing.

**Propose Another Reduction.**—The Dominion Steel Corporation of Sydney, N. S., has made a proposition to the steel workers to resume operations at full time if the men will accept a further wage cut of ten per cent. Several months ago the wages were cut 20 per cent., and the men have been working only one to three days a week.

**Open Montreal Branch.**—The Dominion Steel Products Co., Brantford, have opened a sales branch at 418 St. James Street, Montreal, to handle the various lines made by this company. The new branch in Montreal will be in charge of Maurice P. Shea, who has had considerable experience in machinery and engineering lines. During the war he was overseas in command of a submarine chaser.

**Cut the Wages.**—A cut will be effected in the wages of Winnipeg sheet metal workers to the extent of 7½ cents an hour as a result of a finding handed down by the Joint Council of Industry which has completed the hearing of the trade's wage dispute. The men were previously receiving 90 cents an hour. Officials of the sheet metal workers' union stated that members of the local had expressed their willingness to abide by the council's award.

**Australian Contract Awarded.** — The International General Electric Company, New York, a subsidiary of the General Electric Company, according to report, has been awarded a $1,875,000 contract for switch gear, transformers and other equipment let by the Victorian Electricity Commission for development of coal near the city of Melbourne, Australia. The International bid, according to advices, was $1,000,000 below the lowest combination of British sectional bids submitted.

**Will Extend Plant**—During the visit of the governor-general to Toronto, a visit of inspection was paid to the Baldwin Canadian Steel Corporation plant at Ashbridge's Bay. Responding to the remarks of the visitor regarding the extent of the plant, Mr. Cound, the managing director of the Canadian plant, said it was the intention of the company to make Toronto the greatest tin plate manufacturing centre in the world, plans having been already made for the establishment of a number of additional steel mills at a cost of many millions of dollars.

**New Pumping Station.**—As soon as approval is given by the Administration Commission to the plans for the new pumping station in connection with the Montreal Water Works, construction operations will be commenced. The location for the new station will adjoin that of the one now operating and near the new filtration plant. The building will be amply large to provide for future growth of the city, the initial installation being six 30,000,000 gal. electric pumps, two of which are now in service in the old plant. Room for six additional pumps will be provided in the plans. This new pumping station is to be completed within a year and a half.

**Getting Tenders.**—On behalf of the Chinese Government the Chinese Banking Group is advertising for tenders for the supply of 30 locomotives of the Prairie type, 2 locomotives of the Mikado type, 3 locomotives of the Pacific type, 6 locomotives of the English type, 200,40. Metric-ton all-steel covered wagons and 100,40-Metric-ton all-steel high side open wagons for the Peking-Hankow, Peking-Suiyuan, Tientsin-Pukow and Shanghai-Hangchow-Ningpo Railways. Regulations, drawings and specifications for tenders may be obtained from the head office of the Chinese Banking Group. Tenders will be opened 15th June, 1921, at the head office, Peking Bankers' Association, Chienmen, Peking.

**Want Tenders.**—Tenders are being received by W. W. Pearse, Sec-Treas. of the Board of Education, 155 College St., Toronto, for the following trades for constructing the Riverdale Technical School: (1) Masonry, including concrete work; (2) cut stone; (3) structural steel; (4) ornamental iron; (5) steel sash; (6) carpentry work; (7) roofing and sheet metal work; (8) plastering; (9) marble and tile and terrazzo; (10) linoleum; (11) mastic flooring; (12) painting and glazing; (13) plumbing; (14) heating and ventilating; (15) heat regulation; (16) refrigeration; (17) hydraulic ash hoist; (18) dumb waiter (electric); (19) electric work, including wiring for power and light; telephone system and signal system. Time limit is June 15.

## CHAIN HINTS

Continued from page 39

non-acid, mineral oil which does not dry in the air.

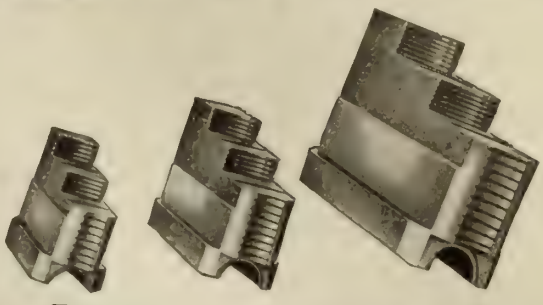
A pure non-acid mineral grease is recommended for chains. In general it is not found advisable to use graphite greases, as they are liable to leave a deposit on the surface of the chain which prevents the entry of further lubricant. On the other hand, excellent results have been obtained with "Gredag." If impregnation is efficient, drives may be run for comparatively long periods after each application of "Gredag." The temperature to which "Gredag" is heated should not exceed 170 degrees F.

**Have Placed Business.**—The Toronto ansportation Commission at its meet- g completed contracts for the air-brake d electrical equipment on the new cars w being built in Montreal. The total ice of the order given is slightly under ,000,000. The order for the electrical uipment was divided as follows: Can- ian General Electric Co., 50 cars; Can- ian Westinghouse Co., 50 cars and nglish Electric Co., 40 cars. With re- rd to the English Electric Co., the or- r given to this firm was for all it was a position to handle at the prsent time. is expected that the company will es- olish a plant on the industrial area at hbridge's Bay, where 48 acres of land ve been acquired. The entire order e air-brake equipment was given to e Canadian Westinghouse Co. The cars ll be installed with four motors of 50- rsepower each, giving ample power r rapid acceleration and high-speed ser- e. Work on the motors has already ogressed so that there will be no de- y in having the cars completed on hedule time.

**China Wants Equipment.**—According information received from the Gov- nment Bureau of Economic Informa- n, 6 Hua Yuan Ta Yuan, Peking, the nistry of communications has notified e Chinese delegate to the Internation- Communications Conference, that ina earnestly welcomes foreign assist- ce in the development of her railways. e Chinese delegate is also instructed emphasize China's strong opposition international control of any Chinese ilways. The Peking-Hankow Railway dministration invites tenders for the llowing equipment: 6 first class sleep- g cars; 6 second class sleeping cars; composite first and second class pas- ger cars; 6 dining cars; 6 third class ssenger cars with restaurant; 10 third ss passenger cars. Drawings and spe- fications may be obtained from the ad office of this railway upon payment the sum of Mex. $25.00. Terms of yment and date of delivery must be early stated in all tenders. Tenders two envelopes sealed and labelled on e outside, "Quotations for 40 passen- r and dining cars," should, by regis- red letter, be addressed to the manag- g-director, Peking-Hankow Railway dministration, not later than June 30, 21. The tenders will be opened before e public at 3 p.m., July 1, 1921.

## Personals

Mr. Logan Waterous, of the Waterous gine Works, Ltd., will sail next week r England. When interviewed by Can- ian Machinery he stated that he is ng to make a study of business meth- s and conditions in the Old Country l does not expect to return to Canada l August.



Sir Joseph Flavelle, Bart., of Toronto, s been elected chairman of the recon- ituted all-Canadian Board of Directors the Grand Trunk Railway. Howard G. Kelley was reappointed director and president of the company. The other directors elected were: J. Narcisse Dupuis, Montreal; E. L. Newcombe, K.C., Deputy Minister of Justice, Ottawa, and Alfred J. Mitchell, financial vice-presi- dent of the Canadian National Railways, Toronto. It is further understood that when the consolidation of the Grand Trunk and Canadian National Railways is finally completed Sir Joseph Flavelle will be appointed chairman of the board which will direct the management of the combined roads.

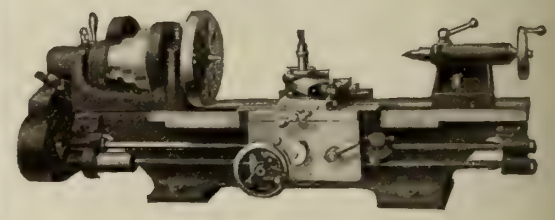
# HEPBURN
## HIGH-SPEED PLANER

WITH a Hepburn High-speed Planer in your shop, you are equipped with what is undoubtedly the country's most efficient planing tool. It is a Canadian product, made in standard size 42" x 42" x 10'. Only the best material is used.

The Hepburn trade-mark is your guarantee of long, unfailing service.



**JOHN T. HEPBURN**
LIMITED
*Engineers and Iron Founders*
18-60 VAN HORNE ST.
TORONTO, ONT.

*We also manufacture Power Presses, Cranes, Pumps, Engines, Cut Gears and Grey Iron Castings.*

# "DALTON SIX"

# Special Machinery Manufacturers

We have frequent requests from manufacturers in the United States for information regarding Canadian firms who are equipped to manufacture their line.

We would like to receive, therefore, the names of any firms who might be interested in inquiries of this kind. We desire the following information:

Name of firm and full address.

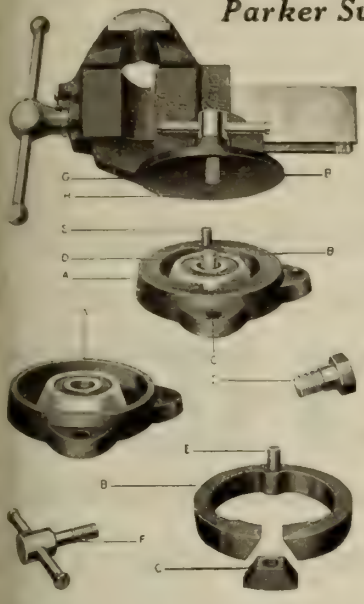
Description of shop and equipment.

Particulars regarding regular line, if any.

Class of work interested in securing and best equipped to handle.

Foundry equipment or connection.

This information will be filed and other necessary particulars forwarded to American manufacturers who are likely to be interested.



**CANADIAN MACHINERY**

*If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.*

# PARKER VISES

*Pioneers 1842* *Leaders Ever Since*

*Parker Superior says--*

7 Reasons Why—
THIRD
—The Swivel Base

The first swivel base above the bench, a patented feature, a challenge to produce its equal. Wedge "C," when drawn up, by bolt "F," expands ring "B" against wall of base "A," forming a positive grip.

**The Charles Parker Co.**
*MASTER VISE MAKERS*
Meriden, Conn., U.S.A.

# SHERMAN

*"Protection"*
DRESSER

*With the Safety Hood*

A handy, capable tool, particularly designed for use on hard, coarse or large wheels where it often proves more economical than a diamond or Diamo-Carbo. It is provided with a safety hood which protects the eyes from flying particles.

Ask for the Sherman Dresser. It touches that "pride" part of a workman's heart. Catalogue on request.

**The Canadian Desmond-Stephan Mfg. Company, Limited**
Hamilton - - - Canada

# Why Waste Time With Dull Files?

It is good business to throw a dull file away and buy a new one. Dull files mean wasted energy and poor results.

Use only sharp files, and you will get more work done in less time.

The following brands do not get dull quickly, they give maximum service:

KEARNEY & FOOT
GREAT WESTERN
AMERICAN
ARCADE
GLOBE

# MURCHEY

## You Don't Have to Scrap Murchey Taps

If you are scrapping your taps when the cutting edge becomes worn you're not getting real Tap Economy.

Murchey Solid Adjustable Taps do not have to be scrapped when the cutting edge is worn. You simply buy a new set of chasers for a comparatively small sum and you have a new tap, equal in accuracy to the best solid tap and at a much lower cost. We give special service in supplying chasers.

Let us send you this tool on approval.

**Write to-day.**

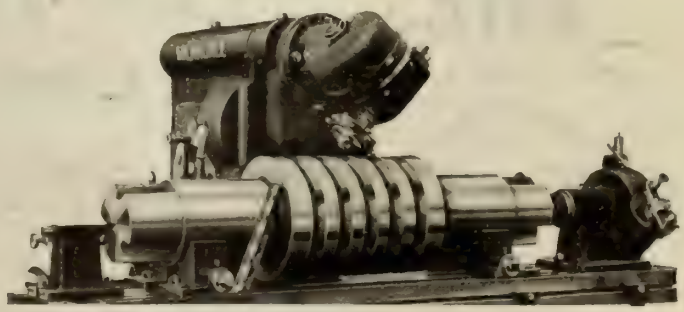
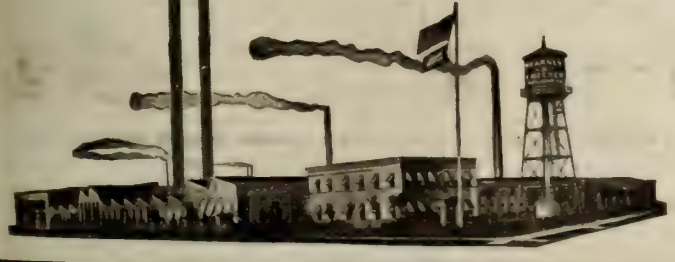
# MILWAUKEE MILLING MACHINES



## Efficient on Light and Heavy Milling



Heavy milling jobs are not unknown to Milwaukee Universal Milling Machines, while delicate and intricate ones are efficiently performed with little effort.

Both light and heavy milling operations are handled with such smoothness and accuracy that the finest results are obtained. Because Milwaukee Universal Milling Machines perform such a wide variety of work, they are particularly well adapted for the tool-room.

The jobs shown in the two illustrations are representative of "Milwaukee" adaptability. The upper illustration shows a jig being bored with a fly cutter. The lower illustrates the milling of a chilled roll with the use of a Universal Milling Attachment.

THE

TRADE K—T MARK

FOUNDRY

GALT, ONT.

## Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

### If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. **Ask us.**

***We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.***

*If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.*

# Canadian Machinery BUYERS DIRECTORY

**If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.**

## DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

# HENDEY

## *Everybody Knows*

Those who have had anything to do with Hendeys know that they are right from experience—the rest know from hearsay.

Take the Hendey 18-inch Engine Lathe for example. It has 36 different threads and speeds through the mounted change gearing, each change being quickly made through controlling handles in the gear boxes.

The apron has double plate construction with safety interlock which prevents the simultaneous operation of the longitudinal feed and screw cutting.

You **know** that these features are well worth while just because they are to be found on a Hendey!

## The Hendey Machine Company

**Torrington, Conn., U.S.A.**

# IMCO TOOLS

Imco Flute Depth

Average Flute Depth

## *A Twice as Deep Reamer*

### For a Twice as Long Life

THE deeper the flutes in a reamer the longer its life and the more holes it will ream before being scrapped. The flutes in "Imco" Reamers are milled almost twice as deep as those in average reamers. Consequently their economical value is nearly twice as great.

Put some pep into your cutting. Use "Imco" tools. Excessive power built into all "Imco" lip drills, reamers, cutters and mill ends.

**Catalogue of 3 and 4-lip drills, reamers and milling cutters on request.**

HIGH SPEED STEEL

The Highest Achievement of British Tool Steel Metallurgy

*The Product of Sanderson Bros. & Newbould, Ltd., Sheffield, Eng.*

H. A. DRURY COMPANY LIMITED

TORONTO MONTREAL VANCOUVER

# *If it's speed you need--*

One trial will prove the advantage of Pratt & Whitney Milling Cutters. No matter what the nature of the work they will give you the highest production the machine is capable of.

They're designed for free, fast cutting. And tempered and seasoned to last longer.

## PRATT & WHITNEY MILLING CUTTERS

Ask us for prices and details on Plain Milling Cutters, Side Milling Cutters. Inserted Blade End and Side Cutters, Screw Slot Cutters, Coarse Tooth Side or Plain Milling Cutters, Involute Gear Cutters, Concave, Convex and Double Angle Cutters, Cutters for Spiral Mills, Roll Thread Die Hobs, Key-Seating and Slotting Cutters. Straight and Spiral Cut End Mills (B. & S. and M. T. Shank), Spiral and Straight Shell End Mills, etc.

And we make formed cutters for special work also. All are backed by the guarantee for goodness that the P. & W. trademark indicates.

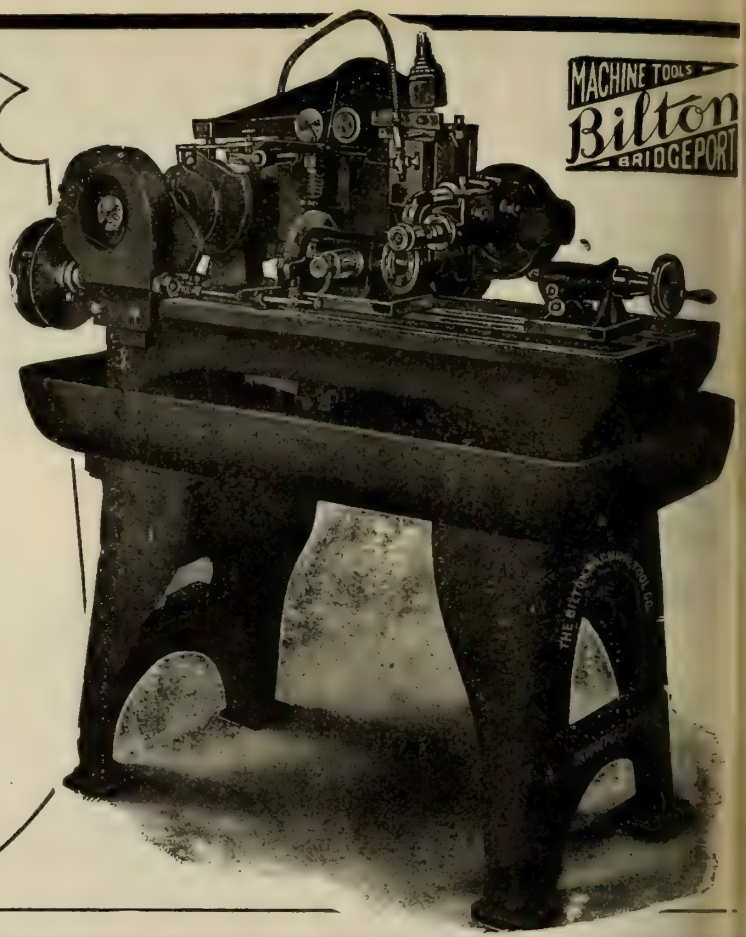
# Bilton

## GEAR MILLERS

WHEN you think of cutting small gears of every description, associate the name of **"Bilton."**

Bilton Automatic Gear Millers conform to almost every phase of small milling work. Their speed, positive and accurate indexing, and easy control make them economy tools on work such as cutting spurs, bevel metres, taps, cylinders, angle gears, and many other operations.



Big business everywhere is adopting the Bilton for high production on accurate work.

Quantity Production of Shafts in Automatic Heat Treatment Furnace.

## PRODUCTION MANAGERS

**The following advantages are secured by the Continuous Method of Heat-Treatment :**

Increased production per unit of floor space.
Reduction in manual labor per unit of production.
Uniformity of product, resulting in decreased scrap, following less dependence upon the human element.
The fuel economy that naturally follows the direct transfer of heat in spent gases to incoming material.
Improvement in working conditions by cooler shop.

**In short, the saving in cost of the finished product due to economy in labor, time, fuel, floor space, decreased rejections, etc.**

Do these advantages appeal to YOU?

*Write nearest branch for Bulletin 217-T and learn whether this method is adaptable to your product and manufacturing conditions.*

TRADE MARK
## BRISTO
REG. U. S. PAT. OFFICE

## PATENTED SAFETY SET SCREWS

**SET A NEW STANDARD**

The distinctive dove-tail slots or flutes of the "Bristo" safety set screw are one of the features which put "Bristo" in a class by itself. "Mushrooming," for instance, is impossible, and splitting or cracking have been removed from the list of your manufacturing worries. As the wrench turns, the unique "Bristo" design contracts the screw; on releasing the pressure the screw tends to expand—a tremendous gripping factor.

## REMOVE ALL GREASE AND DIRT WITH

# Roylite Cleaner

### CLEANS ALL METALS

ORDER a barrel of Roylite Cleaner and watch how speedily and how effectively it removes oil, grease, enamel, paint or any kind of dirt from metal in the quickest and and most economical manner. Never before have you been able to obtain a cleaner which works so quick, retains its strength so long and costs so little as Roylite.

**Lasts Longer**
**Works Quicker**
**Costs Less**

The new Roylite process emulsifies mineral oil and heavy greases which cannot be saponified, by lifting them from the work to top of solution, thereby avoiding the precipitate action, making it unnecessary to throw out solution but merely add small quantities to sustain its strength.

Roylite is the best for preventing rust. It will not discolour or tarnish the brightest surface,

# THE JOHNSON FRICTION CLUTCH

## The Case Against the Countershaft

The old familiar countershaft drive, through cross belts and tight and loose pulleys, stands accused of the following offences against efficiency:

1. Involves needless equipment.
2. Costs too much to set up.
3. Prevents economical and systematic use of space.
4. Operates sluggishly.
5. Multiplies belt troubles and the resultant cost of upkeep.

**Modern practice has discarded the antiquated countershaft for the simplicity and efficiency of the clutch drive direct from lineshaft.**

### Adopt the Johnson Lineshaft Drive

The economical, efficient and durable method of power transmission through friction control.

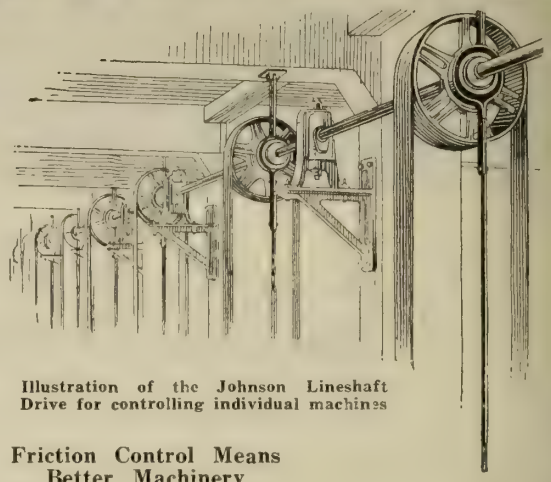

Illustration of the Johnson Lineshaft Drive for controlling individual machines

**Friction Control Means Better Machinery**

Whether it is applied overhead or in the machine itself.

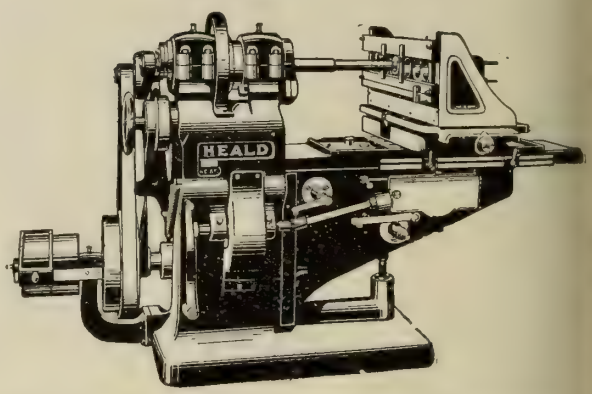
# H.W. PETRIE LIMITED

CANADA'S DEPENDABLE MACHINERY AND SUPPLY HOUSE

H.W. PETRIE LIMITED TORONTO

**The "PETRIE" policy represents the standard in high-grade tools and efficiency in service.**

# MACHINERY and SUPPLIES



REMEMBER the house of H. W. Petrie, Limited, when in need of anything in the shape of machinery and supplies. A colossal stock of machine tools of every description always on hand from which you are assured of getting the exact tool to suit your requirements. Included in this great array are many used tools. They are in good conditions and warranted to give satisfactory service. If you are seeking an opportunity to buy equipment at rock-bottom price don't fail to see our line of used machines.

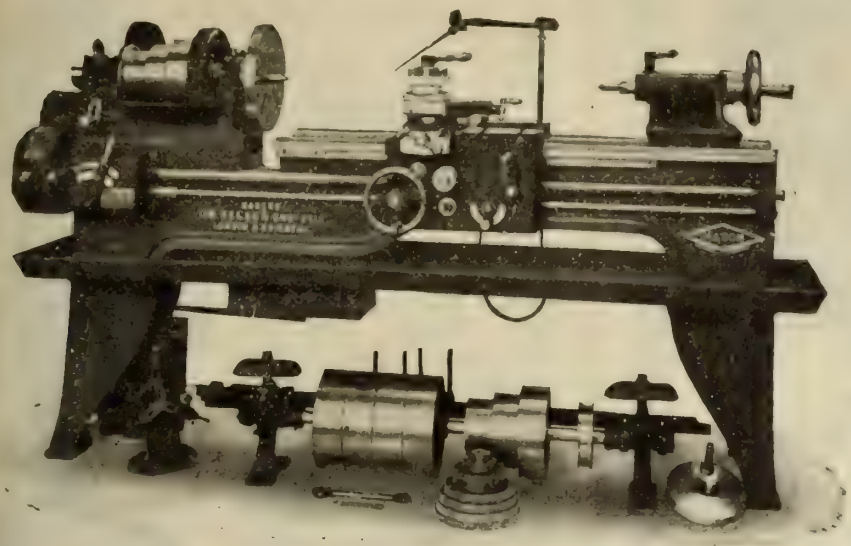
**SERVICE.**—A competent staff of engineers is at your service at all times; submit your problems to them; their advice costs you nothing and it is highly authoritative.

Another factor of importance to remember in dealing with the house of H. W. Petrie, Limited, is this: the quickest of service is always rendered on orders large or small.

**Get the Cream of a Profitable Business**

**Regrinding Cylinders makes used motors better than New**

**Style No. 55 handles all sizes and shapes of cylinders**



There is no business to-day that has the possibilities and which fits as nicely into a small machine shop, automobile repair shop or a concern doing welding, as the regrinding of worn or scored cylinders. Heald style No. 55 is built expressly for regrinding work. It is simple, moderately priced, self-contained, and has a very large capacity and range, easily taking care of singles, doubles, four and six en bloc cylinders.

# Gisholt Turret Lathes and Boring Mills increase production and decrease cost

In the boring, turning and facing of medium and heavy castings, Gisholt has set the standard of output, not only in volume but also in uniformity of accuracy in quantity production. Gisholt excels the individual engine lathe-operator. Exclusive Gisholt features contributing to this result bar contemporaries from equalling Gisholt achievements.

**Gisholt Turret Lathes** range in size from 13 in to 41½ in swing. Change from one class of work to another requires simply a change of tools. The lathe is self-contained and requires no special foundation. Through the friction headstock, back gears and three-speed self-oiling countershaft furnished with machine, a total of 27 spindle speeds is available. Machine may be motor driven. The universal acceptance of Gisholt design and its successful application to varied forms of manufacture are in keeping with the demand for increased production at decreased cost.

**Gisholt Boring Mills** are designed to withstand the severest duty and have ample power to drive high-speed steel to the limit. Supplementing the lathe they complete the equipment necessary for finishing medium and heavy work in the average shop. Gisholt Boring Mills are characterized by rigidity sufficient to withstand strains attending heavy cuts at high speed, by devices insuring accuracy and by improvements for ease of handling. Sizes range from 30 to 84 inch swing.

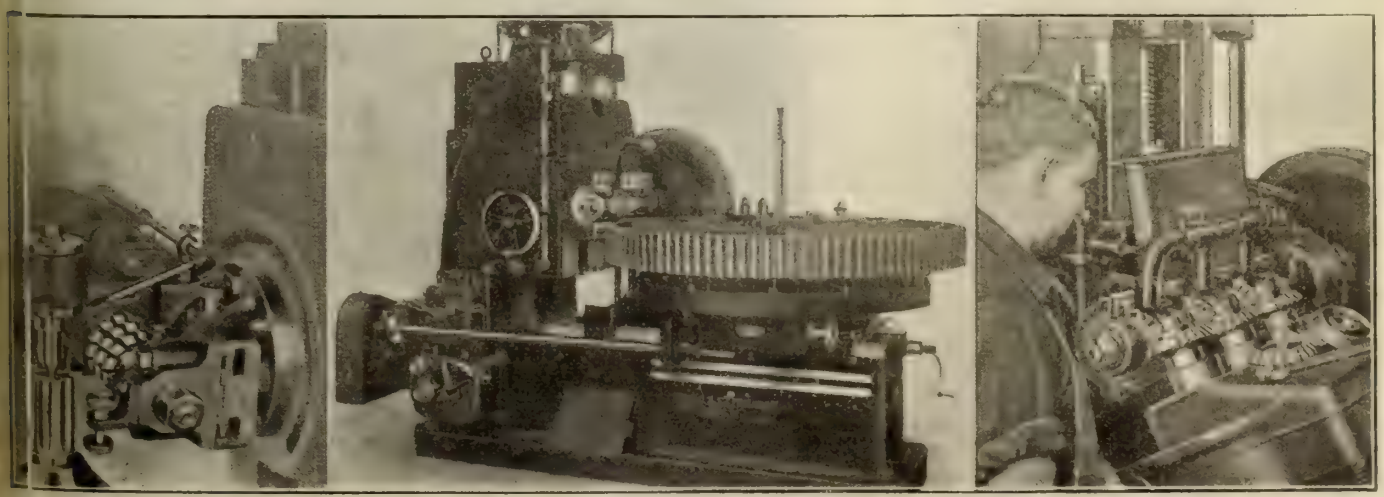
# Generating Gear Teeth For Industrial Uses

Gear cutting has been reduced to a carefully planned operation —Methods of cutting spur-helical, bevel, and worm gears, also splines—Continuous type of gear cutting machine.



By J. H. MOORE

SINCE E. Bodmer in 1839 invented a certain style of milling cutter and hob to cut gear-toothed wheels, the development of the gear cutting art has been a romance in itself. If Mr. Bodmer were alive to-day and were taken through a modern manufacturing plant where a considerable quantity of gears were being cut, he would be apt to exclaim, "Did I actually start all this?" I'm not that he would be flattering himself considerably, for the present method is far removed and improved over his former humble efforts. We now have various methods of producing gears, such as shaping, hobbing, milling, etc., but in all systems the idea aimed at is the same, viz., the turning out of accurate gears in the shortest possible time. In the present article we will consider only one system of gear cutting, that of the Gould & Eberhardt Co., Newark, N.J. To this concern we are indebted for the use of the various illustrations.

LEFT VIEW, FIG. 1.—GEAR HOBBING MACHINE CUTTING SIX HELICAL TIMING GEARS.
RIGHT VIEW, FIG. 9.—A SPECIALLY DESIGNED CONTINUOUS RING GEAR CUTTING MACHINE.

The machines developed by this firm vary in character. There is the automatic gear hobbing machine used for cutting spur, helical and worm gears. These machines are used in both single and multiple spindle type depending upon the nature of the work. Another style is for spur gear cutting only, and is known as the vertical cutting type. A machine of the same vertical cutting type, but having a disc cutter, is used

READING LEFT TO RIGHT, FIGS. 2, 5 AND 6.—FIG. 2 DEPICTS THE CUTTING OF SPLINES; FIG. 5 SHOWS CUTTING A 108 TOOTH 1¾ D.P. GEAR, WHILE FIG. 6 ILLUSTRATES THE ROUGHING OUT OF THREE BEVEL GEAR BLANKS

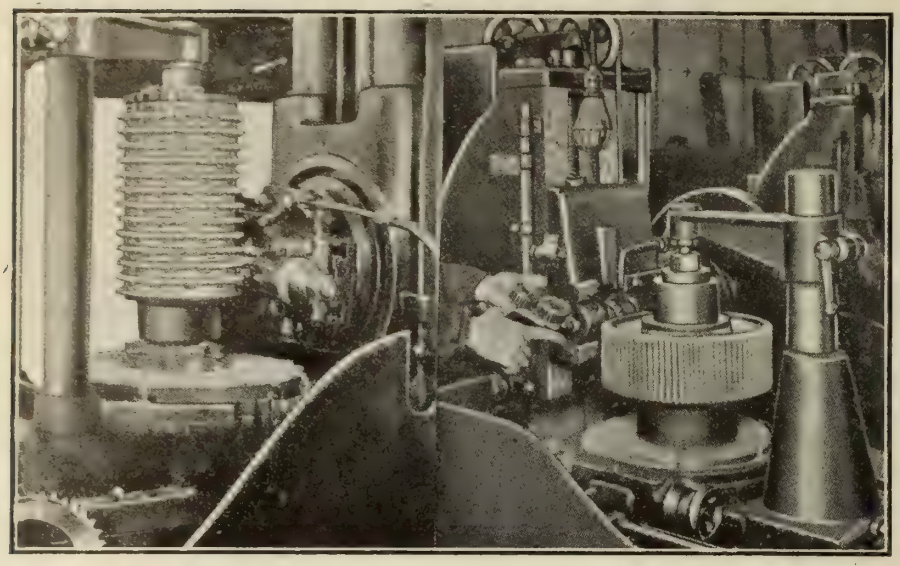


FIG. 3.—CUTTING TWELVE MOTORCYCLE SPROCKETS.
FIG. 4.—CUTTING TWO SPUR GEARS AT ONE TIME.

for cutting spur and bevel gears, while another style of multiple spindle machine roughs out one or more spur or bevel gears at one time.

Ther are also automatic gear hobbing machines for spur, helical and worm gears, while other styles are used for rack cutting. Then there is the bevel gear roughing shaper, and the worm wheel generating machine, the latter type being used for worms only. These, briefly, illustrate the various style machines produced by this one company for the cutting of gears, so that when one considers the other numerous varieties on the machine tool market, the art of gear cutting has indeed been reduced to a carefully planned operation.

At Fig. 1 is shown a gear hobbing machine cutting six helical timing gears. This type of machine is especially designed to cut spur, helical or worm gears, such as are used in the manufacture of automobiles, machine tools and textile machinery. This includes such parts as flywheels, starter rings, steering and transmission gears, helical gears, cam and magneto shafts, splines, speedometer gears, etc.

Fig. 2 depicts the cutting of splines on an automobile driving shaft. The six-tooth spline is on the end of a long shaft, this being inserted in a compression chuck on the machine. A special formed hob is used, and the six teeth are automatically generated. When the hob has fed down the proper distance the machine is automatically stopped. The chief benefit in cutting splines in this manner is that the teeth will not only be accurately divided but identical in shape.

Fig. 3 depicts the cutting of twelve motorcycle sprockets. The diameter of these wheels is 7.490 inches, and they are ⅝-inch pitch, with 36 teeth. The average output per day on one of these machines is 80 sprockets.

An example of spur gear cutting is shown at Fig. 4. Two gears are mounted on the one arbor, each gear being 16.666 inches outside diameter with 2½-inch face. Ninety teeth are cut, the pitch being 6. The blanks are completed in a roughing and finishing cut and are held to a .001 inch tolerance. The two midget gears shown in the operator's hand were cut on the same machine, so this will give readers a fair idea of the range of such machines.

The next photograph, Fig. 5, shows the heavier type of vertical gear cutting machine producing a 108-tooth, 1¾ D.P., 6-inch face steel gear. This type of machine is used for spur gear cutting only, but, owing to its construction, even large gears such as shown can be rigidly supported, and it can be noted from the illustration that there is practically no overhang.

Fig. 6 depicts the roughing out of three bevel gear blanks on an automatic multiple spindle machine. This type of gear cutter is arranged with adjustable workhead, and two or three gears can be roughed out at one time. It can handle a wide range of various angles yet the machine can be arranged with fixed angle head for roughing out spur gears only if so desired. On certain styles of this machine there is a revolving turret, and the operator can unload and reload blanks, while one set of work spindles are in cutting position.

Fig. 7 shows a worm wheel generating machine finishing a worm wheel blank that has 35 teeth of 1.20 inch circular pitch. The blank is made of aluminum bronze, and has the teeth roughly cast to shape to begin with. The output of these gears is 60 every eight hours. Another case of worm wheel cutting that is worth referring to is that of a 28-tooth, 1½-inch circular pitch gear, this gear being completed in 4 minutes' actual cutting time.

At Fig. 8 is shown a rather nice example of worm cutting. In this case the worm is being cut with a special patented hob, but although the finish of the worm speaks for itself, we are unable to give the production time on the piece.

Another interesting case where a certain concern solved the problem of hobbing worm wheels can be told without illustration.

The work in question was the hobbi

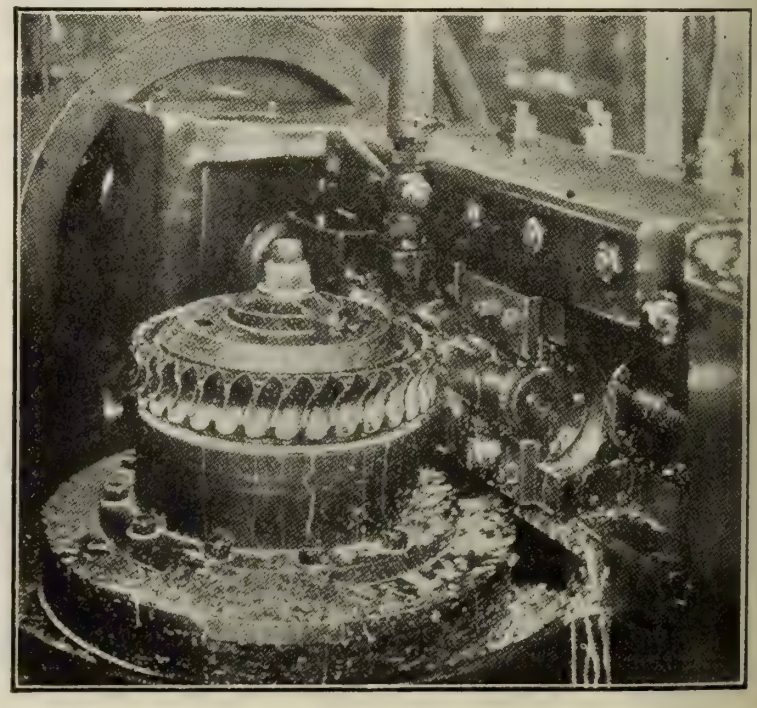

FIG. 7.—FINISHING A WORM WHEEL ON A GENERATING MACHINE.

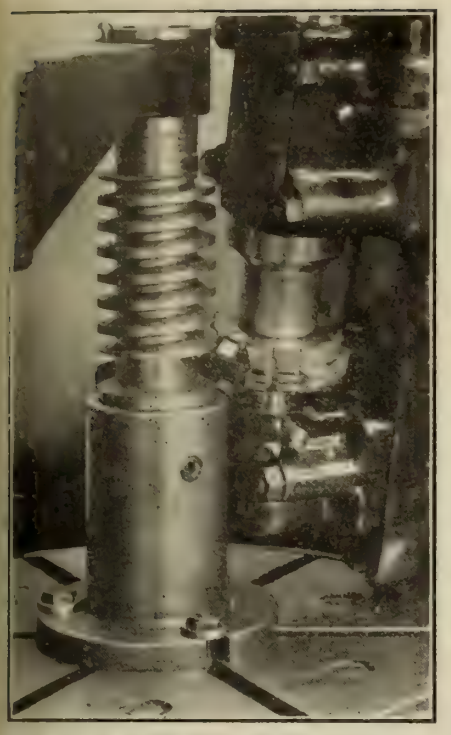

FIG. 8.—A NICE EXAMPLE OF WORM CUTTING.

a very large quantity of worm wheels at necessitated using a very small ameter hob. Due to the diameter of e wheels it was necessary to do the rk in a large gear cutter which was signed for the use of a very large tter and would not permit the use of e very small diameter hob that was cessary in this instance.

They found that the 72 in. G. & E. ar cutter that they had was so well lapted for this work that with the ap- ication of a special cutter spindle drive ey were enabled to handle the job much better than could ordinarily be done. It was necessary to bring the hob spindle forward and this was accomplished by designing and making a special spindle consisting of bearings that fitted into the cutter spindle bearings of the machine and acted as an auxiliary arbor that was driven from the main arbor by a suitable train of gears to maintain the proper direction of rotation of the arbor. The hob was made 2½ in. in diameter, yet cut a worm wheel having 160 teeth, 2½" pitch.

The concluding illustration, Fig. 9, shows a specially designed continuous ring gear cutting machine. This type of gear cutter is of patented design and was made for cutting Ford ring gears. It has an octagon revolving turret head that holds 24 bevel gears at one time. The operation is continuous. The gears being roughed out have 40 teeth and 1-inch face. Two minutes to each gear is the production time. By roughing out a bevel gear preparatory to finishing, much time is saved, not to speak of the easier task it is for the finishing

From the foregoing it will be noted that gear cutting has greatly developed from the days when the old-time mechanic used a single milling cutter to produce his gears. If we had to revert to this process, the present price of automobiles would be sure to take a decided upward trend, but fortunately such a possibility is very remote, in fact we can still look forward to still further development as time goes on.

## HEATING BY ACETYLENE

According to a recent report, acetylene as a substitute for coal in domestic heating in Switzerland has given great satisfaction. For several months, the Palace Hotel, a block of five houses at Lausanne, has been heated by hot water from a central station, where acetylene is generated in a stationary apparatus, mixed with air, and burned in a coil system. In 20 minutes the entire hot water service for the five houses can be raised to 160 to 175 degrees F. Heating the building in midwinter would require nearly a ton of coal per day, but in mild winter weather a comfortable temperature is maintained with a daily consumption of 200 to 500 pounds of carbide.

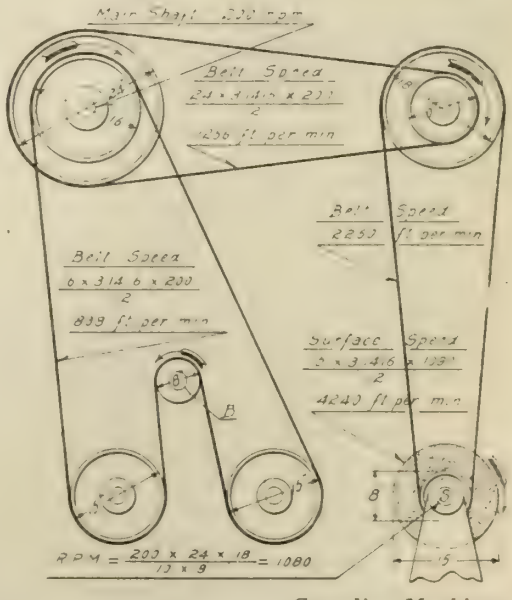
## WELDING MONEL METAL

Monel metal is not difficult for the operator who knows how to weld cast iron or aluminum and how to take care of expansion and contraction. First of all, use a soft flame with an excess of acetylene, so that the second cone extends about ⅝ inch beyond the small flame. The pieces must be beveled and welded as fast as possible, so that the mtal does not get too hot and form blow holes. Use Monel welding flux or borax. Also use rather heavy monel welding rods. When welding sheets of Monel, continues Welding Engineer, bevel the edges and then add enough metal to more than fill up the groove so that the seam becomes heavier than the sheet itself. Try to melt the metal only once, that is, do not go back over your work to try to fill up the cracks. If a crack occurs in the weld do not go over it while hot. Finish up the seam you are welding, then let it cool; take a hammer and bump the place where the crack is, over a width about three or four times the thickness of the metal, then weld over. When cool beat th esheet back as it was, but never attempt to hammer the sheet while hot.

# *Transmission Problems*

## *FINDING SPEEDS OF BELTING AND SHAFTS*

Belt speeds are controlled by the speeds of the shafting and the diameters of the pulleys. If the speed of one shaft and the diameters of all the pulleys in the train are known, the r.p.m. of any of the other shafts may be determined, or vice versa.



The r.p.m. of the driving shaft multiplied by the diameters of all the driving pulleys will equal the speed of the final shaft multiplied by the diameters of all the driven pulleys.

The belt speed in ft. per min. is equal to the circumference of the pulley in feet times the r.p.m. of the shaft.

Example: To find the surface speed of the grinding wheel in the sketch, when the main shaft is running at 200 r.p.m., multiply the r.p.m. (200) of the main shaft by the diameters of the driving pulleys (24 and 18) and by the circumference of the grinding wheel (15 x 3.1416) and divide this by the diameters of the driven pulleys (10 and 8) multiplied by 12, to get the answer in feet.

$$\frac{200 \times 24 \times 18 \times (15 \times 3.1416)}{10 \times 8 \times 12} = 4241.16 \text{ ft. per min.}$$

$$\text{Speed of shaft B} = \frac{200 \times 16}{8} = 400 \text{ ft. per min.}$$

# Making A Combination Drill and Countersink

Details of construction—Operation list with tools used—Eight operations necessary to complete the drill—Special fixtures used in various operations—Description based on requirements for local plant use.

By F. SCRIBER

ALL machine work turned on centers requires center holes on the ends in order that the work may run true after each machine operation. Numerous methods are employed in accomplishing this object, but the general practice is centering by means of what is known as the combination drill and countersink. The purpose of this article is to describe a convenient method for the small shop for manufacturing this serviceable tool in reasonably large quantities for local plant needs.

Views of the centering tool are shown in detail in Fig. 1, and features of construction are emphasized that are not generally appreciated by the average user. These tool bits are usually made from semi-high or high speed steel. They are machined on both ends, very often one end being larger than the other, hardened and ground to the desired angle and dimension. In Fig. 1 is also shown an end and sectional view of the tool. These views are given more particularly to show the milling, two grooves being milled opposite through the drill diameter X. The extreme end of the drill, for a length equal to B, is milled straight. From there on, for a distance C, the bottom of the groove is tapered with an increasing thickness at the bottom, while the radius A is equal to the radius of the milling cutter. The flutes of the tool point are milled helical, and the cone portion Y, representing the countersink, is backed off so that the front edge of the groove will form a cutting edge. The parallel portion of the small drill end is also backed off. Re-grinding of the drill point is necessary owing to the wear, but it is essential that care be taken not to get the drill too short, as it will destroy the accuracy of the center in the work, owing to the fact that the lathe center will bear against the end of the hole and not on the countersunk portion. This is shown at the extreme right of Fig. 1.

While apparently a very simple tool, it is one which is nevertheless rather difficult to make without the aid of special tools. The number to be made will determine the extent of the tool equipment. While machinery of special design would be employed when making these center bits in large numbers, the tools and fixtures here described would be quite adequate for making sufficient for a factory using them in large quantities. A sequence for machining these combination drills is shown on the chart Fig. 2. This list gives the operation

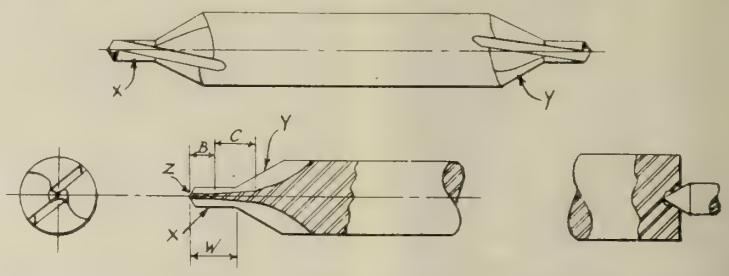

FIG. 1.—DETAILS OF COMBINATION DRILL AND COUNTERSINK.

number, the name of the operation, a column of "tools used" with brief description. The fourth column gives the various tool numbers, the fifth column gives the number of the machine on which the tools are to be used, while the last column indicates the department in which the work is performed. It will be noted from this sheet that the first operation is to cut the combination drills and countersinks to length and point; this is done on a speed lathe equipped with a collet, cutting-off tool, and a center rest for supporting the blanks while being cut off. This machining arrangement is shown in Fig. 3, where the work A is held in the collet B in the lathe spindle. The rods are fed through the spindle in the usual manner and fed against the stop or center C held in the tail stock of the lathe. The work is cut off by the form cutter supported in the block D on the cross slide. The jaw X in the steady head E is adjusted to support the work when cutting off.

The second operation, that of turning one end and relieving the angle, and also the third operation performed on the opposite end, are accomplished on a lathe with a turret carrying a roughing and a finishing tool, the former being shown in Fig. 4. The work is mounted in a collet A, with the work projecting out sufficiently to permit the hollow mill B to operate on the work. On the nose of the lathe spindle is attached a simple fixture that carries on its face a flange in the form of a cam, the contour of which corresponds to the relief to be given to the countersink of the drill bit.

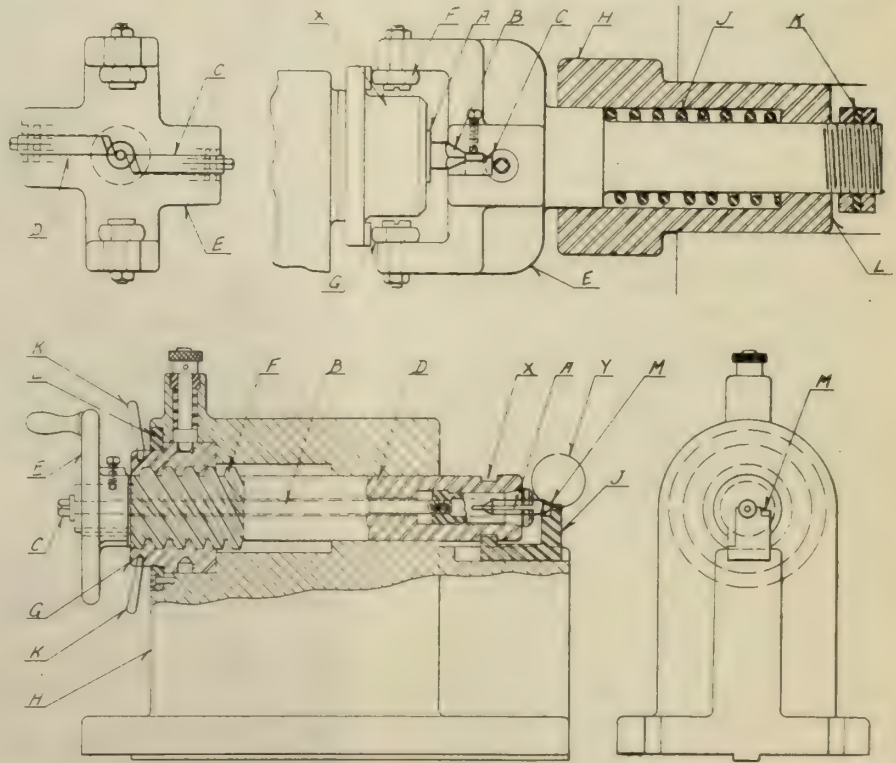
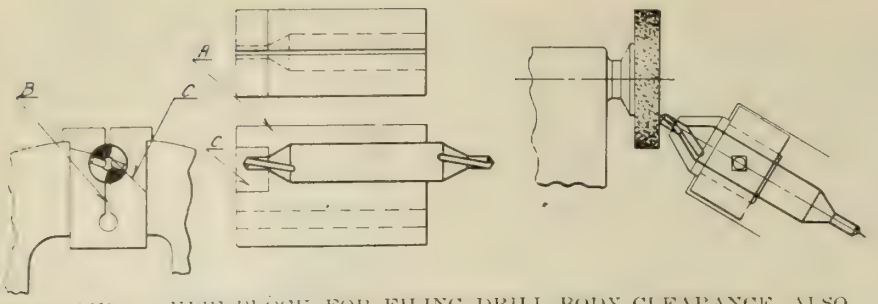
FIG. 2.—OPERATION LIST SHOWING VARIOUS TOOLS USED.

UPPER VIEW, FIG 3.—SHOWING THE ARRANGEMENT OF TOOLS FOR CUTTING OFF BLANKS.
LOWER VIEW, FIG. 4.—TOOL FOR ROUGHING TURNING POINT HELD IN CHUCKING LATHE.



The purpose of this cam will be better understood by reference to Fig. 5, which shows the finishing tool in operation, the roughing tool being used for cutting away the bulk of the metal while the finishing tool completes the relieving of the tapered portion. In Fig. 5, A and X represent the chucking members. The drill is being turned by the two cutters C and D; these tools are adjusted and are mounted in the body of the holder E and held by set screws. The two rolls F and G are supported on the outer forks of the tool holder on studs, as shown. The shank of the holder is held in the sleeve H, which is supported in one of the holes of the turret in the usual manner. The compression spring J keeps the working end of the tool in a forward position, the check nuts K limiting the travel of the holder. In operation the tools C and D commence turning the drill portion of the bit, and when doing so the turning head E is in the expanded position. When sufficiently forward the rollers F and G come in contact with the cam surface, and the head begins to oscillate back and forth, and this goes on until the countersink is finished with the desired relief. This motion, it is understood, has no effect on the parallel portion of the work.

The fourth operation, that of milling the grooves, is accomplished by means of the special fixture shown in Fig. 6, which is mounted on the table of a hand miller. The work is held in a collet, operated by means of the draw rod B passing through the spindle. At the rear of the spindle is the hand wheel E secured to the spindle D by a suitable set screw. The spindle has a coarse pitch thread F that engages with the nut G. The tool steel block J, used for supporting the outer end of the work, moves laterally with the movement of the spindle, the groove X allowing the spindle to revolve while retaining the relative position of the block J. The circle Y represents a cutter in position for cutting one of the flutes in the work.



In operation the hand wheel E is turned, thus advancing, and at the same time revolving the work through a certain distance and angle, to cut the desired helical groove in the drill and countersink.

To mill the groove at the opposite end the bushing G is indexed 180 degrees, the index pin locking the nut in either position. The handles K are used for this purpose, the ring L retaining the nut in a fixed lateral position. Provision is made on the hand miller for the simultaneous lowering of the knee of the machine after the straight portion of the flute has been milled, giving the rear portion of the groove a reducing depth. The lowering of the table is controlled by a beveled portion M on the side of the sliding block J coming in contact with a roll on the cutter arbor. The machine is locked against longitudinal feed during these operations.

The combination drill and countersink is now practically completed, the remaining operations simply consisting of filing the relief on the drill diameter, hardening, tempering, polishing and grinding the point. To relieve the drill diameter a filing block as shown in Fig. 7 is employed. The block A is held in a bench vise and is split at B and hardened so that it will have sufficient spring for self relief. For backing off the drill the block is cut away at C to serve as a guide. It will be noted that when the work is placed in the machine for milling or in the vise for filing, it should be located radially with the relief of the countersink; this can be done by

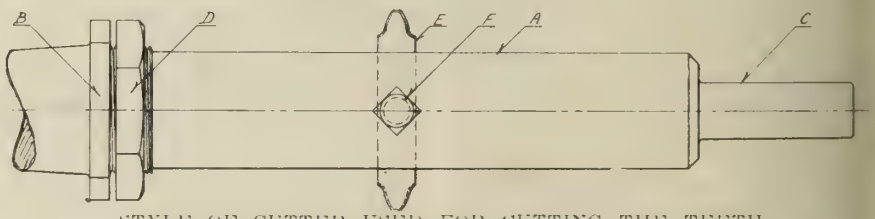
UPPER VIEW, FIG. 5.—TURNING AND RELIEVING TOOL USED IN CHUCKING LATHE.
LOWER VIEW, FIG. 6.—FIXTURE IN WHICH COMBINATIONS ARE MILLED.

FIGS. 7 AND 8.—VISE BLOCK FOR FILING DRILL BODY CLEARANCE, ALSO METHOD USED TO GRIND THE DRILL POINT.

setting the high point of the relief tangent with a line on the sliding block in the case of milling, or in line with the surface C when using the filing block. Hardening and tempering is accomplished in much the same manner as is customary for small tools having similar characteristics.

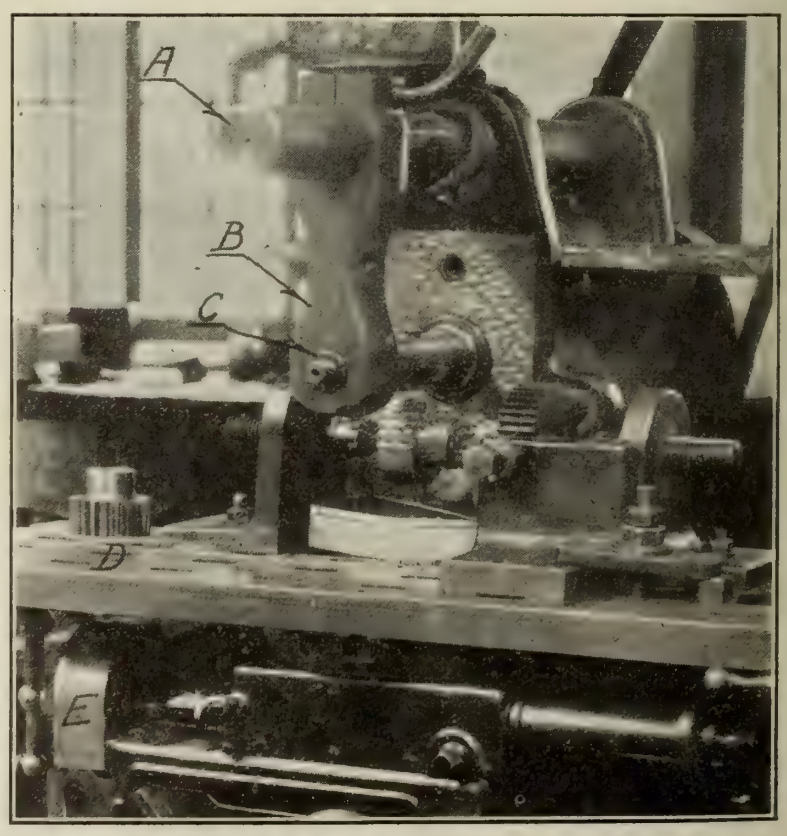
Fig. 8 shows a suitable arrangement for grinding the point of the drill; this consists of a bushing mounted in a rotary fixture, similar to those of regular drill grinders, where the drill is oscillated across the side of a wheel, resulting in an accurately ground point.

These tools would by no means give the maximum amount of production for a job of this kind, but what they are intended for, and do provide, is a good method of making this particular tool, and still keeping within theoretical limits of accuracy. They will do this economically, may be used for various sizes with slight modification of holding fixtures, and are of that type of tools found most useful in plants making their own small tools used for production manufacture.



## MILLING ON A SLOTTING MACHINE

By J. H. R.



The accompanying article illustrates and describes a very interesting method adopted by the superintendent of a Montreal shop for meeting the needs of milling requirements without the purchase of a milling machine. While the range of work possible with this device will be considerably less than on a standard miller, it enables the shop to perform a lot of odd jobs that would otherwise be very difficult to accomplish. As will be seen from the cut, a small tool room Dill slotter has been utilized as a basis for the "milling" machine.

The crank shaft of the slotter was removed and a parallel bar A, inserted, this bar being extended at the front to carry the swinging arm support B, which may be clamped at any desired position. In place of the pinion drive shaft of the slotter a special spindle was used in the same bearings, but of additional length to carry the small feed cone on the rear end. The front end of the spindle has a tapered hole to receive the end of the boring bars or cutter arbors. Owing to the spindle being solid the bars or arbors are provided with special facilities for removing same from the bland tapered hole. The end of all bars are made to fit the hole in the adjustable split bush C. The work table D, is bolted to the regular circular table of the slotter. Power feed has been provided by means of the worm and worm wheel E, the latter being fitted with a special friction clutch, operated by a knurled nut on the feed screw. A bracket is secured to the lower part of the frame at the rear to support the back end of the telescopic shaft connecting the feed cone with the worm shaft. The short vertical feed screw of the slotter was replaced by one of sufficient length to raise the table high enough for milling operations, a hole in the base permitting the lowering of the table to its lowest extremity.

The illustration shows the machine set up to cut teeth in small pinions, the blank being held on a short arbor supported on centers specially made for this work from old angle brackets. These brackets were bored and threaded in the same jig to assure identical center height. Indexing is obtained by the use of a gear on the work arbor, with the same or divisable number of teeth. The indexing "finger" is a pointed screw held in an angle plate clamped to the work table. The cutting of the small pinion was performed by means of the double-ended fly-cutter E, shown in the line sketch, the shapes of the ends varying slightly to provide a roughing and finishing cutter. The collar B, is provided with flats which fit a corresponding slot in the nose of the spindle. Removal of bar is accomplished by means of the nut against the face of the spindle.

STYLE OF CUTTER USED FOR CUTTING THE TEETH.

GENERAL VIEW OF THE MACHINE IN OPERATION.

# Canadian Machinery Drafting Course, Part 2

The block type of lettering—Sections and section lining—Geometrical drawing—Various geometrical definitions—Six problems in geometry, including how to construct an angle equal to a given angle.

By J. H. MOORE

N the previous article, appearing in the June 2nd issue of Canadian Machinery, we discussed briefly the subject of mechanical drawing; the use of various instruments, and the making of plain Gothic style of lettering. We will next consider the block type of lettering shown at Fig. 1. At first sight this looks like a difficult style, but in reality it is very simple, for it is a mechanically produced style of lettering. The T-square and triangle are all that are required. For illustrative purposes we will suppose the letters are to be 5-16 inch high, and ¼ inch wide, except M, which is 5-16 inch wide, and W, which is ⅜ inch wide. The thickness of the lines in all cases will be 1-16 inch and the distance between any two letters of a word will be 1-16 inch, except when A follows P or F; where V, W or Y follows L; where I follows F, P, T, V, W or Y; where T and A are adjacent, or A and V, W or Y are adjacent. In these cases the bottom extremity of A and the top extremity of P, T, V and W are in the the eye will largely decide and discover same vertical line, etc. In other words, the proper spacing to use in such cases.

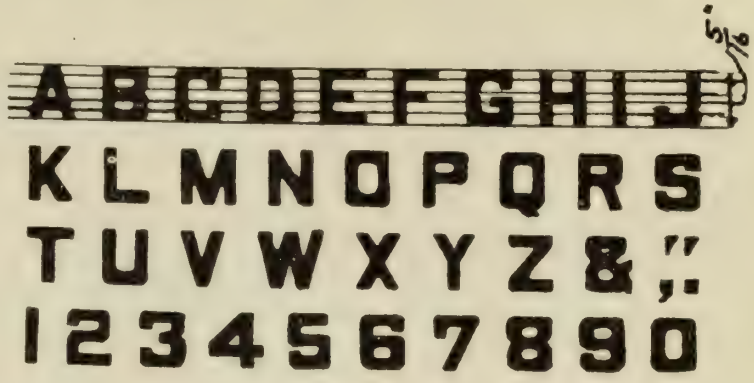


FIG. 2. PRACTICE THIS STYLE OF LETTERING CAREFULLY.

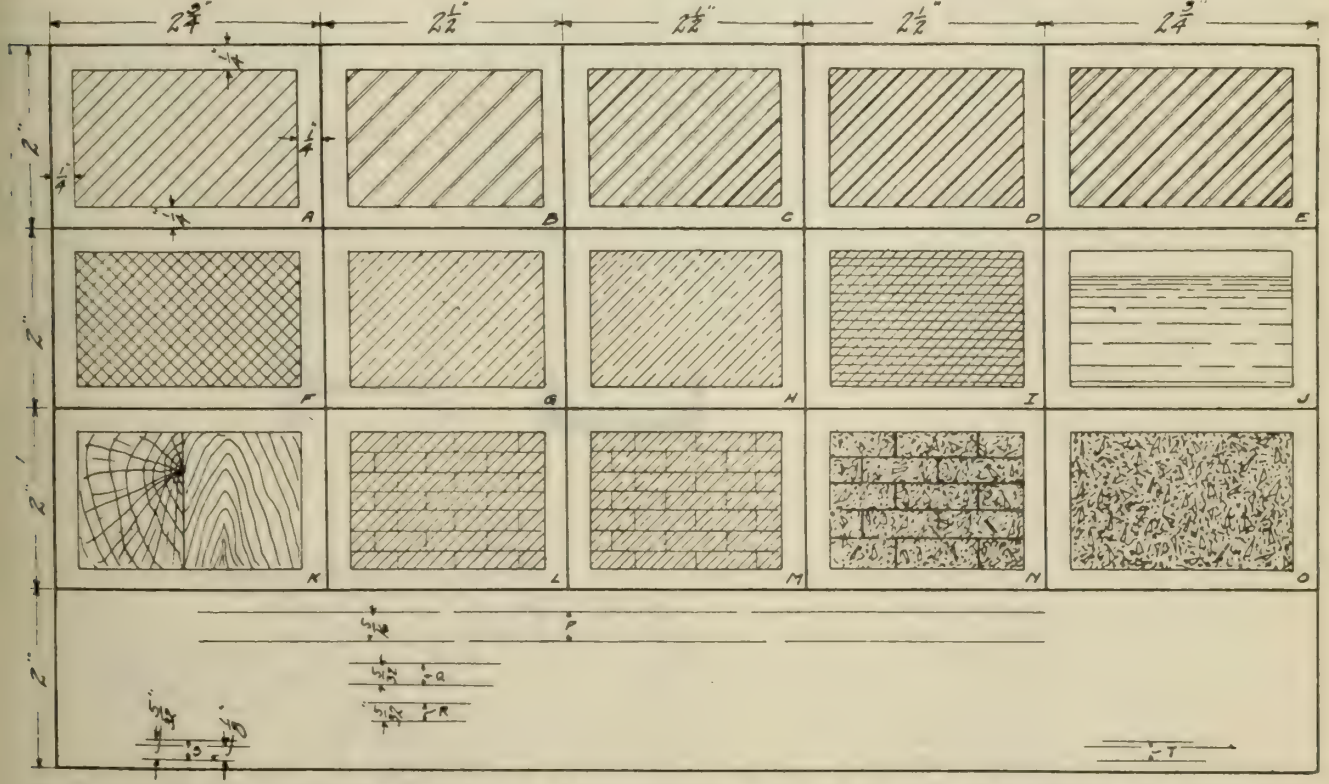
The letters being composed of straight lines, they can be made with the T-square and triangle. Draw six horizontal lines 1-16 inch apart, to represent the thicknes of the lines at top, center and bottom; then draw vertical lines with the triangle; these lines also being 1-16 inch apart. Having drawn the guide lines, proceed to construct the different letters, but in pencil only. After laying out the letters, start to ink in, using the regular ruling pen. It is a wise plan to ink all vertical lines first, then the horizontal lines, and last of all the oblique lines. By doing so, the chances of blotting are less, at the same time the letters are built up in their natural sequence. After the outline is completed, fill in the letters with an ordinary pen nib. Before leaving the subject of lettering, we feel that the necessity of care



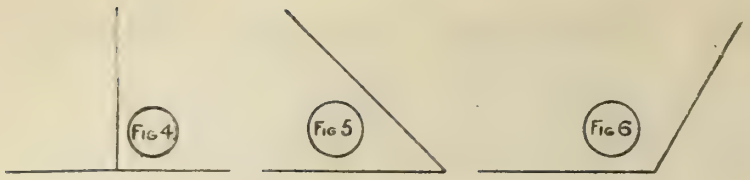


FIG. 2.—STUDY THE DIFFERENT MATERIALS REPRESENTED. MEMORIZE THEM IF POSSIBLE. IN LOWER PORTION OF THE PLATE LAY OFF SPACES AS SHOWN AND PRACTICE PRINTING. PRINT THESE WORDS, "CANADIAN MACHINERY DRAFTING COURSE." PRACTICE PLATE ON SECTIONING, ALSO PRACTICE IN GOTHIC STYLE LETTERING. PUT THE DATE IN LEFT HAND LOWER CORNER AND NAME IN RIGHT HAND LOWER CORNER. KEEP THE DRAWING AS A RECORD OF YOUR ADVANCEMENT.

FIGS. 4 TO 6. SHOWING VARIOUS TYPE ANGLES.

and practice should be emphasized. It is only by practice that you can make perfect.

### Section and Section Lining

When we speak of a section through a piece of work, who do we mean? Simply this, that to show clearly what otherwise would be hidden, and represented on the drawing by dotted lines, we cut clean through the center of things, or in fact through any portion of an object or objects to show its various details. To make such points as clear as possible, the various parts are section lined, these lines representing the material from which the parts are made. Unfortunately there is no universally adopted standard, thus a combination of lines in one drawing office may mean steel, while in another office the same lines might represent cast iron. In the majority of drawing rooms, however, the combinations are alike; and Fig. 2 illustrates 15 of these so-called standard shading or section lines.

Students should study these various materials closely, so that they can tell immediately, from memory, the material that any section lining represents. Following are the materials shown in Fig. 2. A represents cast iron, B cast steel, C malleable iron, D wrought iron, E wrought steel, F copper or zinc, G brass or aluminum, H composition, I insulating material, J water, L brick, M fire brick, N concrete blocks, and O represents concrete. Students should make it a point to lay out this exercise to scale, drawing in the various sectional blocks, for it will not only be good practice, but will help them remember the style of sectioning used for the different materials. Where lines are too near each other to be sectioned, they are simply blackened in as shown at Fig. 3. This style of sectioning is most frequently used for sectional views of structures composed of plates, rolled sections such as I beams, angle irons, etc.

On entering further into the question of sections we find that the lines do not always run in the same direction. For example, refer to Fig. 3. Here we note a sectional view that shows more than one piece. It is a general rule among draftsmen that each part of the same piece is section lined in the same direction, irrespective of its continuity. By this means, after one has grasped the principle of sectioning, they can easily ascertain if at various parts of the section the same piece appears. In a later lesson we shall tell the student how to make sections from sketches and objects, but the chief idea at present is to get a good grasp on the real principle of sectioning.

Referring again to Fig. 3, let us discuss it in detail. The line A B is of course the center line, threfore this view would be termed section through A B. It will be noted that portion C is shaded similar to section A, Fig. 2; this we find to be cast iron. Parts D and E are sectional similar to section B, Fig. 2, and on looking this up we discover the material is cast steel. Note, however, that the section lining on these two parts run in opposite directions. This shows that they are two separate pieces. Thus we arrive at the conclusion that the view shows three different pieces: a cast iron holder C; a cast steel bushing D; and a nose piece E. In planning to make a sectional view, about the best method to tackle the proposition is as follows: Imagine you have a saw in your hand and that instead of the materials being various steels, iron, etc., they are all of soft wood. You are about to saw through some determined portion of the assembled pieces, calling the line of direction A B. Start work (that is, in your imagination) and wherever your saw touches that is where section lining must go. Thus, if you suddenly hit a hole with your saw, the section lining will show all around the hole, but not at the hole. This explains why a portion of the piece C is not section lined, for there is a hole running through the part up to the bushing D. Let us impress on students the necessity of neat work. Space the shading equally, for nothing looks worse on an otherwise well prepared drawing than poor section lining.

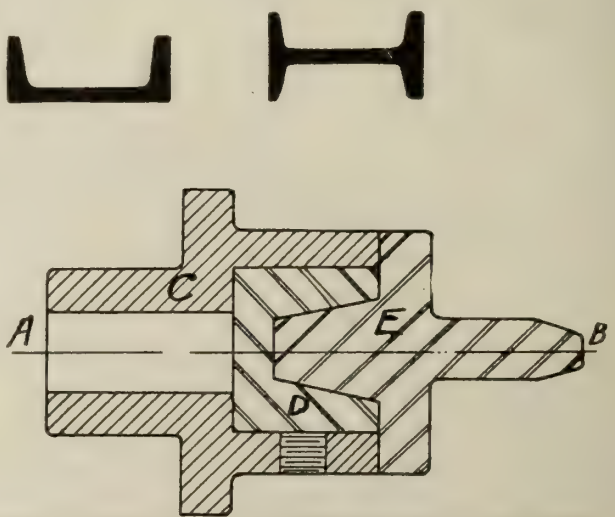

FIG. 3.—THE IDEA OF SECTIONING IS APPARENT FROM LOOKING AT THESE SKETCHES.

### Geometrical Drawing

For the sake of the average student we would like to omit the subject of geometrical drawing, but believing that a groundwork on the subject is absolutely essential, we will take up a few of the more important problems. The average mechanic may not see the force of learning this subject as part of mechanical drawing, but let him rely on our judgment, read about these problems, and later on he will find out why we included them in the course.

Geometrical drawing is the art of becoming acquainted with the various lines and figures; what particular properties these figures have, and what bearing they have on mechanical drawing. One of the main ideas in geometric drawing is accuracy, so be sure you follow the problems carefully, drawing up the examples accurately, otherwise the benefit of this section of the course is lost. In geometrical drawings we speak of definitions which of course mean an explanation of the various lines and figures involved in the study.

### Geometric Definitions

For example, a point is used to mark a position and has neither length breadth nor thickness.

A line has length only. It is produced by the motion of a point.

A straight line is one that has the same direction throughout. In other words it is the shortest distance between any two points.

A curved line is one that constantly changes its direction. Sometimes it is termed a curve.

A broken line is one made up of several straight lines.

A horizontal line is one that has the direction of a line drawn upon the sur

face of water which is at rest. In other words a line parallel to the horizon.

Parallel lines are lines which lie in the same plane, and are equally distant from each other at all points.

A vertical line is one that lies in the direction of a cord suspended from its upper end, having a weight at its lower end. It is a line which is perpendicular to the horizon.

An oblique line is one that neither conforms to the vertical nor horizontal.

Examples of lines already spoken of are as follows:

Lines drawn with the T-square are all parallel to each other. A line drawn by means of the triangle on its straight side, together with the aid of T-square, is a vertical line. A line drawn with the sloped side of triangle with same conditions as above will be an oblique line.

If two lines cut each other they are called intersecting lines, and the point where they cut is called the point of intersection.

An angle is the measure of the difference in direction of two lines. The lines are called sides and the point of meeting the vortex. The size of an angle is independent of the length of the lines.

If one straight line meets another, as in Fig. 4, so that the two angles thus formed are equal, the lines are termed perpendicular to each other, and the angles formed are known as right angles.

Should the angle be less than a right angle it looks like Fig. 5 and is termed an acute angle.

Should the angle be greater than a right angle it is termed an obtuse angle and appears as shown at Fig. 6.

Before going further into the other various definitions let us consider these already given as sufficient for this first portion on geometrical drawing. In this way the student will not have to carry in his head too many definitions at once, but will be able to concentrate on the particular ones he requires.

For the sake of practice, prepare the plate shown in Fig. 7, making the border lines of the drawing 8 inches by 13 inches. Divide this space into six spaces as shown. Commencing at problem 1, here are the methods of working out these problems.

### No. 1—To Bisect a Straight Line

To construct: First draw a straight line AB 3¾ inches long. With A as a center and a radius greater than one-half of the length of the line, describe an arc of a circle on each side of this line AB. With B as a center and the same radius, describe arcs as before, intersecting the first two at the points C and D. Join C and D by the line CD, when the point E, when it intersects AB, will be the required point. In other words, AE=EB, as E is the middle point of AB.

This problem could also be termed erecting a perpendicular line to a straight line from its middle point, for the line CD is in the middle of AB and is perpendicular to it.

The next problems, Nos. 2 and 3, can be classed under the one heading, namely, to erect a perpendicular to a given line from a point in that line. We will take up two cases. In problem 2 we will consider the task when the point is near the center of the line.

Draw AB 3¾ inches long. Let C be the given point on the line. With C as a center and any radius, such as CD, describe two short arcs cutting AB at the point D and E. With D and E as centers, and any convenient radius greater than CD, describe two arcs intersecting at F. Draw CF and that line will be perpendicular to AB at the point C.

In problem 3 we take up a case where the point is near the end of the line.

Draw AB 3¾ inches long. Suppose C about ½ inch from the end of the line as shown. With any point D as a center and a radius DC, describe an arc cutting AB at C and E. Draw ED and produce it until it intersects the arc at the point F. A line drawn through F and C will be perpendicular to AB at the point C.

### Problem 4—Through a Given Point to Draw a Straight Line Parallel to a Given Straight Line

First, let AB be the given line 3¾ inches long. Let C be the given point. With C as a center and any convenient radius, describe an arc DE intersecting AB at E. With E as a center, and the same radius, describe the arc CF intersecting AB at F. With E as a center and a radius equal to the chord of the arc CF, describe an arc intersecting DE at D. A straight line drawn through D and C will be parallel to AB.

### Problem 5—To Bisect a Given Angle Where the Sides Intersect Within the Limits of the Drawing

To construct. Let ABC be the angle to be bisected. Draw the sides AB and BC 3¾ inches long. With B as a center and any convenient radius describe the arc DE intersecting AB at D and BC at E. With D and E as centers, and a radius greater than the chord of half the arc DE, describe two arcs intersecting at F. A line drawn through F and B will bisect the angle. In other words, ABF will equal FBC.

### Problem 6—To Construct an Angle Equal to a Given Angle

Draw AB 2½ inches long, and the line BC 2½ inches long. The angle formed by these lines may be any convenient size; in this case we will call for 45 degrees. This angle ABC is the given angle.

Now draw DE, a horizontal line 2½ inches long, and let D, the left-hand extremity be the vortex of the angle to be constructed. With B as a center and any convenient radius, say about 1½ inches, describe the arc FG, cutting both AB and BC. With D as a center, and the same radius, draw the indefinite arc HJ. Next set the compass so that the distance equals the chord FG. With H as a center and a radius equal to FG, draw an arc, cutting HJ at J. Through D and J draw a straight line. The angle JDE will now be equal to the angle ABC.

In drawing these exercises use a good 4H or 6H pencil, making sure it is perfectly sharp. Draw the pencil lines lightly, then after completion ink them in as shown at Fig. 7. Memorize the problems if posible, and above all, be accurate, as otherwise you may as well not do them at all. In our next lesson we will go further into the subject.

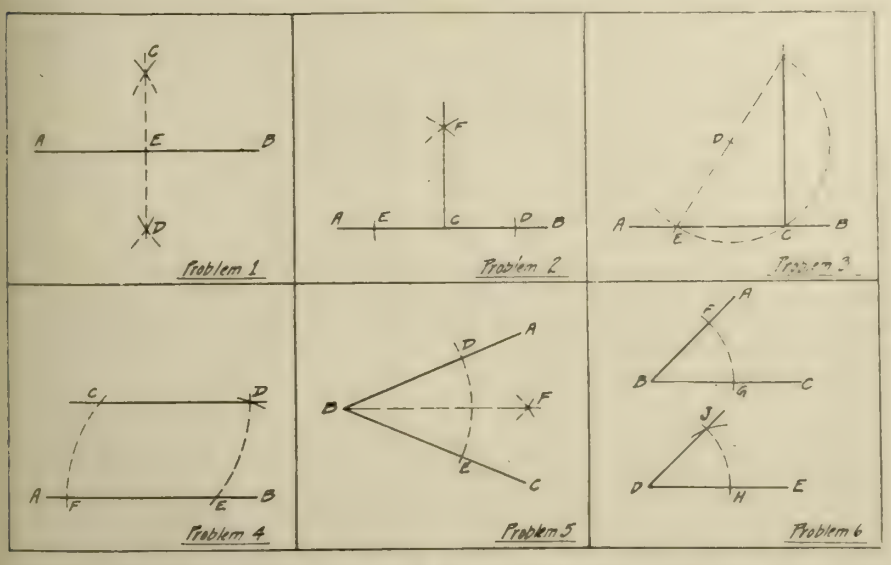

FIG. 7.—TO BE OF ANY VALUE, THIS PLATE MUST BE ACCURATELY DRAWN.

# One Method of Manufacturing Ball Bearings

The plan adopted by an English concern—Description includes annealing—Removing of fins—Lapping—Inspection, and other interesting operations. Method of inspecting balls especially noteworthy.

THE manufacture of ball bearings is at all times an interesting study; in fact very little is known about the process. In a recent article in Engineering, the method employed by the Ransome & Marles Bearing Co., Ltd., Newark-on-Trent, is discussed, and following are some of the interesting points brought out, the subject being confined in this case to the manufacture of the balls themselves.

The greatest interest for the ordinary engineer lies in the manufacture of the balls themselves as the product is unique amongst engineering articles and the methods of manufacture have been heretofore considered as trade secrets. The raw material is in the form of wire or rod according to the size of ball required. It consists of chrome steel, the proportion of chromium varying with the size of the ball. For a ½-inch ball the percentages of the important alloys would be about as follows: Chromium 1.28, carbon 1.06, manganese 0.5 per cent. Originally it used to be the custom for the first operation to consist in turning the balls from the rod in a lathe, and this practice is still followed by some makers.

This concern, however, always forge their balls, as this not only saves material, but improves the quality of the material by reason of the mechanical work done upon it. If balls of both respective kinds are strongly etched with acid, the forged balls are attacked less severely and over a smaller area, the difference in the corrosion being sufficient to enable the method of manufacture to be determined with practical certainty. The corrosion is always worst on the end grain of the material, and the areas of the grain are smaller in the case of the forged balls, while the grain is denser because of the deformation of the metal by the dies.

The material from which the balls are to be made is of course put through the usual chemical and physical laboratory tests before it is issued to the works. It has to be correct as to composition and crushing strength, and furthermore a piece cut from the bar, one and a half diameters long, has to stand crushing cold to two-thirds of its original length without showing any sign of flaw or splitting. Balls of ½ inch diameter, and over, are forged hot, the first operation being to shear the bar into slugs, each of sufficient length to make one ball. This is done cold. These slugs are then heated in a gas-fired muffle, and placed one by one in the fixed hemispherical die of the stamping press. The ram contains an exactly similar die, and one blow converts the slug into a sphere with a thin fin of extruded metal round its equator. The ball is ejected from the die and rolls down an inclined chute into a tray beneath the adjoining press. The operator here picks it up with tongs while still red-hot and places it on the flashing die. The descending ram forces it through this die, thus shearing off the "flash" and leaving the ball practically spherical. These presses will turn out about 3,600 one-inch balls in a day of eight hours.

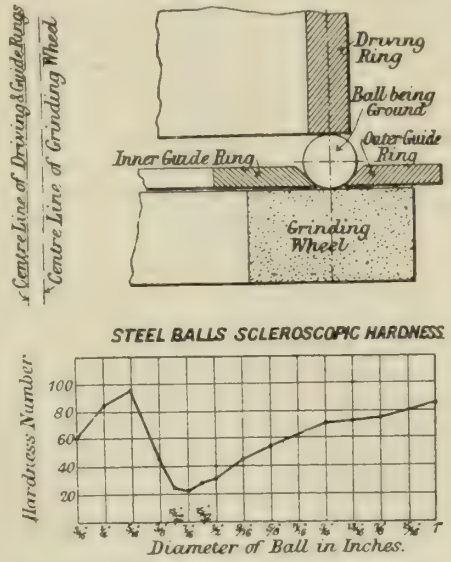
### Annealing

The forged balls are next annealed in gas-fired muffle furnaces and then rough-ground all over. This is one of the most interesting processes from the manufacturing point of view. The machines on which the operation is performed have a vertical spindle carrying a large annular grinding wheel, the upper flat face of which does the work. Immediately above this wheel is a fixed annular plate, the inner edge of which is bevelled to an angle of about 45 degrees. When the machine is working a circular bevelled plate occupies a position centrally in the fixed outer ring, so that between the edges of these plates there remains an annular vee-shaped groove, open at the bottom. The annular groove is filled with a row of the forged balls, upon the top of which a heavy horizontal wheel descends, pressing them into the groove. This wheel rotates, causing the balls to roll round and round the groove, and the portion of them which projects through the open bottom of the groove is acted on by the grinding wheel running at a high speed immediately beneath. The grinding wheel is fed upwards by a micrometer feed, which is automatically tripped at a predetermined point. The spindle of this wheel is mounted eccentrically to the ball groove, so that the wear on the wheel takes place evenly across its face. The eccentricity of the grinding wheel together with the fact that the path of the ball on the inner side of the groove is longer than its path on the outer side causes the ball to spin about a vertical axis as well as roll about a horizontal one, and the consequence is that it is effectively ground all over. The work is done dry, the dust being removed by an exhausting arrangement fitted to each machine. Each machine will take about one hundred ½-inch balls, and will rough grind them in about twenty minutes. They are removed by lowering the centre bevelled plate by means of a lever at the side, when the balls of course run out. The next operation is to finish-grind them, which is done on precisely similar machines using a finer grade of stone. The balls are then about 0.006 inch over the finished size and are, of course, in the soft condition.

To make the account of ball-making complete, we must now return to the manufacture of the smaller sizes of ball, which, as we have said, are not hot forged. The steel for these balls is used in the form of coils of wire or rod, and the balls are first formed on cold-heading machines. The wire, which for the ⅜-inch ball suitable for the bearing which we have previously described would be 0.275 in diameter, is automatically and intermittently fed through the machine by means of a ratchet device. It emerges through a quill, and the projecting end is sheared off by a knife fitted with spring fingers which hold the slug and carry it forward to the dies. As these close on it, the fingers are withdrawn, and the slug is pressed into a ball having a fine fin around its centre. The balls, so formed, drop into a tray as the dies separate, and are then annealed in gas-fired muffles.

### Removing Fins

The next operation is to remove the fins, or flash as it is termed. For this purpose the balls are put into a knurling machine in which they are repeatedly rolled between the fixed and moving faces of a pair of case-hardened steel plates. The opposing faces of these plates are furnished with annular semi-circular grooves having knurled concave surfaces, between which the balls roll. The plates are mounted on a horizontal axis, one being stationary and the other driven by the machine. The stationary plate has a parallel gap from the edge to the centre, this gap being horizontal when the plate is mounted. The balls being rolled round the grooves by the motion of the running plate, descend to the top of the gap and escape from the machine into a spiral chute, down which they flow and are conducted to the ends of the grooves on the lower side of the gap. They become mixed in the chute so that they enter different grooves for their next revolution, and this process is continued until they have all their fins and scale removed. These same machines are used for the subsequent lapping or the balls, the knurled gap-plate being then replaced by a gap-plate with plain grooves and a grinding wheel being substituted for the running plate.



After knurling, the cold forged balls

are rough-ground, and finish-ground exactly as described in the case of the hot-forged balls, and from this point onwards the operations carried out on both types are identical.

The next operation is to harden the balls. They are heated in rotary furnaces by a continuous process. These furnaces have in their interior a hollow spiral pipe, and at every revolution the inlet end of the pipe receives a certain number of balls which gradually roll towards the outlet end as the furnace rotates. The principle is in fact similar to that employed in the Archimedean screw. The spiral pipe is kept heated by gas flames playing into the interior of the furnace, and the balls traverse the furnace so slowly that they remain for a long time at the "soaking" heat, and finally fall out into a bath of oil or water according to size, in which they are quenched. An electric pyrometer enables the temperature of the furnaces to be maintained at a degree which has been found experimentally to suit the size of ball and the class of steel of which they are made, the usual temperature being in the neighborhood of 800 degrees C.

After hardening, the balls are tempered by being boiled in oil or water, according to the size, and the results required. They are then descaled by being run in tumbling barrels along with a mixture of potash and grit, and a second course of barrelling with potash and fine abrasive finishes their surfaces sufficiently for the hardness test. This test consists of crushing to destruction in a hydraulic press ten balls from every batch. Each ball is crushed separately between a pair of hardened steel dies, the pressure required to do this being noted on the hydraulic gauge. Bags are wrapped around the dies before the pressure is put on and the operators are further protected by means of a movable steel guard as a properly hard ball bursts under the pressure with almost explosive force, and the flying fragments might cause serious injury. Should any of the balls be soft, or should they not all show the same hardness within reasonable limits, the whole batch is rehardened.

It is curious to note that should a ball be subjected to pressure greater than about half the ultimate crushing pressure, and then be removed from the machine, it will almost certainly fly to pieces suddenly and spontaneously within a space of time varying from a few minutes to a few hours. An examination of the fragments of a crushed ball is also interesting. At the points between which the pressure is applied a sharp pointed cone of crushed metal seems to be formed, and the driving of these cones into the body of the ball appears to be the ultimate cause of its bursting. It may be mentioned at this point that the scleroscope hardness test conveys practically no useful information as to the hardness of a ball. The rebound of the hammer, which gives the scleroscope reading, is much more dependent upon the size of the ball than upon its hardness, and in fact if a series of balls of equal hardness be tested under the scleroscope, the size of any ball can be fairly confidently stated if the respective scleroscope reading is known. The scleroscope number, moreover, is not by any means a simple func-

UPPER VIEW.—METHOD OF GRINDING THE BELLS.
LOWER VIEW.—ACTUAL SCLEROSCOPE READING OF A SERIES OF BALLS OF GRADUALLY INCREASING SIZES.

tion of the size of the ball. Small balls give a high scleroscope number which diminishes to a minimum for balls of about 7-16 inch diameter, and then increases more slowly as the size of the ball tested increases.

The sketch with this article shows the actual scleroscope readings of a series of balls of gradually increasing size, from 3/16-inch diameter to 1-inch diameter, and all of equal hardness within commercial limits. The shape of the curve is very curious. The value for a 7/16-inch ball is just about the same as would be obtained for a ball of equal size, but in the soft state. The reason for the strange results of the scleroscope test when applied to balls is not yet fully explained. It appears to be due to the reflection back of the pressure wave produced by the blow, the reactive effect on the hammer depending upon the phase of the returning wave. This will, in turn, depend upon the size of the ball.

### Lapping

Returning once more to questions of manufacture, the balls when passed for hardness have next to be "lapped." This word is really a misnomer, or at any rate it does not convey any idea of the process to an ordinary engineer. The lapping machines are the same machines as used for the knurling process, described above. The plates used are of chilled cast-iron and the grooves are semi-circular in cross-section, with a narrow rectangular trench cut back into the plate at the centre of each of them. The grinding wheel is a disc, one of the flat faces of which presses the balls into the grooves and drives them round the fixed plate by its rotation. As in the case of knurling, the balls escape at the place where the slot occurs in the fixed disc, and pass down a spiral chute to re-enter the grooves below the slot. A stream of paraffin plays on the balls passing down the chute. The grinding wheel is forced against the balls with a pressure of from 400 to 600 pounds, the exact pressure being indicated by a gauge on each machine.

There are altogether three separate lapping operations, all exactly similar to each other, except that the stones are successively of finer grade. The balls leave the first lapping machine from three to ten thousandths of an inch over size. They leave the next machine about one ten-thousandth of an inch over size and leave the last machine practically dead to size and with a high finish. A good deal more has to be done to them, however, to obtain the perfect polish which is characteristic of the commercial article. The operation next after lapping consists in tumbling the balls in a barrel containing rouge powder and scraps of leather. This is continued for many hours and the balls emerge from the process highly polished. They are next given a final shine in another tumbling barrel containing a solution of potash, remaining in this barrel for perhaps eight hours to sixteen hours. There is, however, a limit to this treatment because a too long-continued immersion in the potash solution spoils their color by developing a brownish tinge. The final treatment which they undergo consists in being tumbled in yet another barrel along with leather and sawdust, which dries them and gives them the very last touch in polish.

During the later stages of the lapping processes and also during the tumbling operations, the balls are very carefully gauged, as the object of all these operations is to produce a batch of balls not only as perfectly polished as it is possible for them to be, but also all of exactly the required size. In this connection it must be remembered that "exactly" has a meaning which verges upon that of "absolutely," for in a ball-bearing factory a ten-thousandth of an inch is regarded as a "door step." The final gauging of the balls cannot take place until they have had twelve hours or so to lose the warmth which they contain upon removal from the drying barrel. During this interval they are visually inspected for cracks, flaws or soft spots.

This work is done by girls who acquire a most remarkable skill in detecting instantly any defect which could hardly be seen by the untrained eye even when pointed out. It might be thought that there was a likelihood of defects of the kind we have mentioned escaping notice, but it is found that the results of the visual inspection are perfectly reliable as a second inspection by a different operator will produce identical results.

### Inspection

Inspection is carried out in a well-lighted room, the girls being seated at a table and each provided with a light shallow rectangular tray into which ten or a dozen balls are placed simultaneously. The bottom of the tray is lined with white paper, the surface of which is reflected on the underside of the polished balls, and renders any defect in them visible to the trained eye. A momentary glance at the row of balls suffices, and then they are rolled about by the motion of the tray, so as to present a fresh part of their surfaces for inspection. When the whole of the surface has been examined and any defective ball picked out, the remainder are tipped into a box for gauging. One of the defects which the visual inspection has to reveal is the presence of soft spots in the otherwise hard balls. It is not clear how these can occur, but they do. Their existence is shown by a kind of brown cloudiness on the surface of the ball, which would never be noticed, or its significance suspected, except by the trained inspector. The softness is only relative to the glass-hard surface of the rest of the ball, but if the ball be tried for hardness with a file, it can be seen under the microscope that while the normal surface is absolutely unaffected, the soft spot has been marked by the file teeth. The microscope also shows the reason for the visibility of a soft spot. The surface there is minutely pitted, and lacks the high polish which the various operations have produced on the harder parts. It need hardly be said that absolute cleanliness is necessary for visual inspection to be practicable. The inspectors all wear gloves of soft chamois-leather, and also have chamois-leather cloths to place the balls on, as the slightest trace of grease would make examination impossible. A girl will inspect about 5,000 ½-inch balls in an eight-hour day, and the number found imperfect may be estimated from the fact that in a batch of 20,000 which had just been inspected at the time of our visit, 344 were rejected for soft spots, 81 for cracks and 247 for surface defects. This, however, is somewhat more than the usual percentage of rejections.

The balls which have passed visual inspection are next sent to the gauging room, which is kept at a constant temperature. The actual process of gauging consists in passing every individual ball through a ring gauge, which is set by a standard ball known to be accurate within the limits of possible measurement. Every ball which leaves the works is guaranteed to be within plus or minus 0.0001 inch of standard size. The girls who do the gauging push the balls through the plate, and determine by the sense of touch whether they are within permissible limits of size. Those thrown out, or about which there is any doubt, are tested on a minimeter which gives a highly magnified reading of the measuring points by means of a long pointer.

Although the guaranteed accuracy of the balls is within plus or minus 0.0001 inch of size, the actual variation in size between the balls in any bearing manufactured by Ransome and Marles is very much less than this. The balls are graded into a total of eight sizes intermediate between the limiting permissible sizes. The difference in size between the balls of any two successive groups is therefore only 0.00002 inch, or one fifty-thousandth of an inch, and all the balls in one bearing are taken from the same group. This almost incredible accuracy is of course not guaranteed, but it is aimed at and practically attained in the works we are dealing with. The method of grading is for the gauger to place all acceptable balls in one or other of three different heaps, according to the ease or otherwise with which they pass through the ring. There is thus an over-size heap, an under-size head and a standard heap. The two former heaps are then passed again through ring gauges, the latter being set to sizes fractionally higher or lower than the standard size. By repeating this process the whole of the balls are sorted into groups of size, varying, as we have said, by only about one fifty-thousandth of an inch. On the occasion of our visit to the works of the Ransome and Marles Bearing Co., Ltd., we picked out three balls at random from one of the boxes into which they were being sorted, and we saw them afterwards measured on a Societé Genevoise measuring machine, when they were found to be all exactly 0.00002 inch less than standard size.

## CAPACITY OF ROUND TANKS.

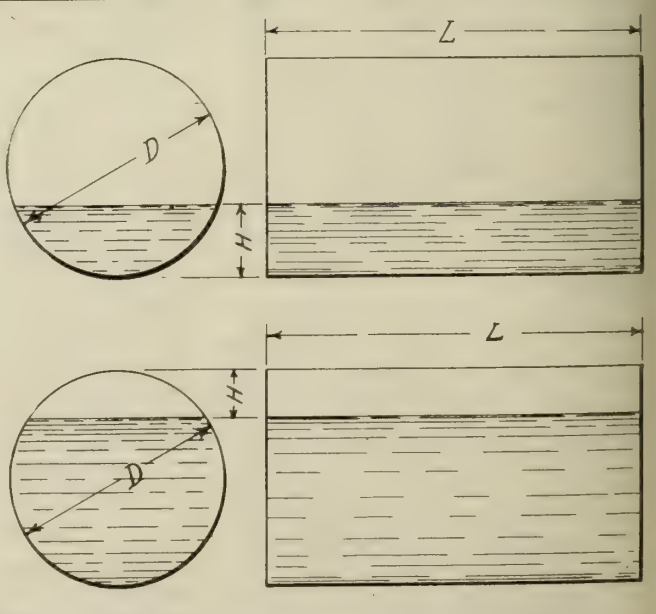
$D$ = Diameter in Ft. $H$ = Height in Ft.

Area of Segment $= \frac{4H^2}{3}\sqrt{\frac{D}{H} - .608}$

Vol. of $H = \frac{4H^2}{3}\sqrt{\frac{D}{H} - .608} \times L = X$

$H$ Capacity in U.S. Gal. $= X \times 7.48$

$H$ Capacity in Br. Imp. $= X \times 6.23$



This Formula Is Good Up To Half The Tank.

FOR TANKS OVER HALF FULL.

Vol Contained In Tank.

U.S. Gal. $= \left(.7854 \times D^2 - \frac{4H^2}{3}\sqrt{\frac{D}{H} - .608}\right) \times L \times 7.48$

Br. Imp. $= \left(.7854\ D^2 - \frac{4H^2}{3}\sqrt{\frac{D}{H} - .608}\right) \times L \times 6.23$

Canadian Machinery.

IT WILL BE GOOD POLICY TO CUT OUT THESE CHARTS, USING THEM FOR FUTURE REFERENCE PURPOSES.

# Improve Your Powers of Perception—Try This Contest

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Six contestants submitted correct lists to the May 19th contest, these being Peter Hubert, Sydney, Cape Breton; J. R. Smith, Montreal; A. J. Murray, North Sydney, N.S.; George Land, Peterboro, Ont.; B. Back, Hamilton, Ont.; and J. A. Scarsbrook, Winnipeg, Man. By our elimination method, Peter Hubert, 70 Park St., Sydney, Cape Breton, was declared the winner. Who will be the next?

**CONTEST FOR JUNE 9TH ISSUE**

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1—Something that skilled machinists prefer
2—Where time is expensive.
3—Five accusations against a familiar sight in the machine shop.
4—Something noted for its uniformity.
5—How to secure increased production per unit of floor space
6—A method of getting over the rush order problem.
7—Something that is merely an indication.
8—A product said to cause lower operating costs.
9—Something said to be always superior
10—How to make every dollar a judicious investment.
11—A product that has a part, that is said will not work loose.
12—Something that represents strength and economy.

**These are Correct Answers for List from May 19th Issue:**

1—C. E. Johansson, Inc.
2—Hodge Mfg. Co. of Canada, Ltd.
3—John Bertram & Son Co., Ltd.
4—H. W. Petrie, Ltd.
5—Alfred Herbert, Ltd.
6—Nova Scotia Steel & Coal Co., Ltd.
7—Canadian Ingersoll Rand Co., Ltd.
8—Ford-Smith Machine Co., Ltd.
9—Brown-Boggs Co., Ltd.
10—Canadian S. K. F. Co., Ltd.
11—Canadian Hart Products, Ltd.
12—Canadian Link Belt Co., Ltd.

## Closing Date for This Contest is June 30th

# How To Select The Proper Broach For The Work

SOME very interesting points are brought out on the use and care of broaches in a recent booklet issued by the Velco Manufacturing Co., Greenfield, Mass. Here are some of the paragraphs included:

The field for the application of broaching is wide, and a great increase in production follows its adoption. When there has been dissatisfaction it is likely to have arisen from misapplication or misunderstanding of the requirements, on the part of the broach maker. The broach is in every sense of the word a production tool. Under proper working conditions and with careful use, a broach will produce a large number of accurate holes at a very low cost per piece. Being a delicately hardened tool, the broach is easily broken by careless or improper use. Frequent breakage causes serious loss and inconvenience. Production must be held up until replacements can be secured, and the broken broach has no salvage value.

Care in selecting the proper broach for the work at hand, proper preparation of the piece to be broached and a correct set up of the broach in the broaching machine will go far toward reducing breakage to a minimum.

### Selecting the Proper Broach

In designing a broach it is essential that the manufacturer know fully the conditions under which the broach is to operate. If the information tabulated below is given, a satisfactory broach should result:

(a) Kind of material broach is to cut. (b) Length of the work, i.e., length of surface actually to be broached. (c) Method of preparing the work for broaching. Whether drilled, bored or cored. (d) Size of the smallest hole in which broach must start. (e) Give every dimension of the finished hole desired, and the limits of accuracy expected. Note —A broach should be made to the high limit as it may be ussed longer before wearing undersize. Very close limits of accuracy increase the cost of the broach due to increased cost to manufacture. (f) The make and size of the broaching machine on which the broach is to be used.

It is desirable that the manufacturer be supplied with a blue print or sketch of the piece to be broached. When possible send a few sample pieces so that the broach may be tested before shipment. If it is impossible to send a sample of the work, should the limits be close, the gauge which will be used in the broacheld hoe will aid the manufacturer. Upon receiving the broach do not attempt to judge its accuracy by measurement of the broach itself. The accuracy can be correctly determined only by measuring the hole produced. Experience and experiment have taught the broach maker that certain allowances must be made for the spring of the metal. This differs with various metals and is often allowed for in the design of the broach. Hence the dimensions of the broach may differ from those of the hole it will produce.

A broach should be used only in the work for which it was designed. If the broach is to be used for several lengths of work, the maker should have this information. Then, if the variation is not too great, the broach may be designed to meet the conditions. If the piece to be broached is greater than that for which the broach was designed there will not be sufficient chip clearance. The teeth will fill with chips and rough up the surfaces of the hole. If the strain becomes too great, a broken broach will result. On the other hand, if work is much shorter than the intended capacity of the broach is attempted, there will not be enough teeth in the work at one time. The broach will drift, or crawl, and produce an off-size hole.

Short pieces may be stacked on the broach until the necessary length is reached. This is dangerous practice, unless the length of each piece is greater than that of the tooth pitch of the broach (the distance between tooth faces) a piece may drop down between the teeth of the broach and cause breakage. In stacking work it is very important that both faces of each piece are finished true with the bore.

### Preparing the Work

The hole in which the broach is to start should be drilled or bored. It is possible to start from a cored hole, but the sand and scale soon impair the accuracy of the broach. The face of the work that rests against the face plate should be finished, and be true with the bore. Accurate results are impossible if the latter rule is not observed. Certain soft "stringy" steels often tear out at the edge of the hole. This can be eliminated and the finish improved by heat treating so that a Scleroscope reading of from 25 to 30 is obtained. If material much harder than this is encountered excessive wear on the broach will result, and can be avoided by annealing the work.

### Lubrication

The cutting lubricant plays an important part in the broaching operation. There is a wide difference of opinion as to the best lubricant for the various metals. Those mentioned have been found successful in many plants. Soda and water will improve the finish of cast iron and wash the chips from the broach teeth. For steel a soluble oil of the following composition is popular and inexpensive: 2½ pounds soda ash, 3 gallons mineral lard oil, 50 gallons water. Mix soda and lard oil together in ten gallons of water, then add 40 gallons of water. Kerosene is frequently added to this mixture if the steel is very tough. In broaching aluminum, turpentine or gasoline have proved satisfactory.

The method in which the cutting lubricant is applied is important. The stream of lubricant should be directed into the hole at the top, so that as much as possible will enter with the broach. Square broaches should be pulled with a corner upward. The cutting lubricant then flows down and aroundboth sides and does not spatter off, as would be the case if the flat surface were upward. Spline broaches should be so slotted that the channel between two of the splines will be at the top. The channel then serves to conduct the cutting lubricant into the hole with the broach.

### Broaching "Kinks"

As a broach becomes dull a tendency to drift may develop. This is overcome by sharpening the teeth on the opposite side from that toward which the broach tends to drift. Dull broaches may be greatly improved by sharpening with an oil stone. Very dull broaches should be returned to the maker for re-grinding.

It is difficult to re-grind a broach without special equipment. Even with a suitable grinder it is seldom that a satisfactory cutting edge is obtained unless the operator understands fully the proper cutting angles of the teeth and relieving to prevent back taper. The operator should be provided with a stiff bristle brush with which he may remove the chips from the broach teeth as they emerge from the work. See that all chips are removed from the teeth before attempting to place a new piece on the broach.

Should a piece become stuck on the broach during the cut, by the breaking of the broach teeth or crowding of chips in the teeth, further damage to the broach may be avoided by placing the broach in a lathe and turning the piece away. If the broach has no centers, or it is more convenient, the piece may be sawed through on a milling machine or with a hack saw.

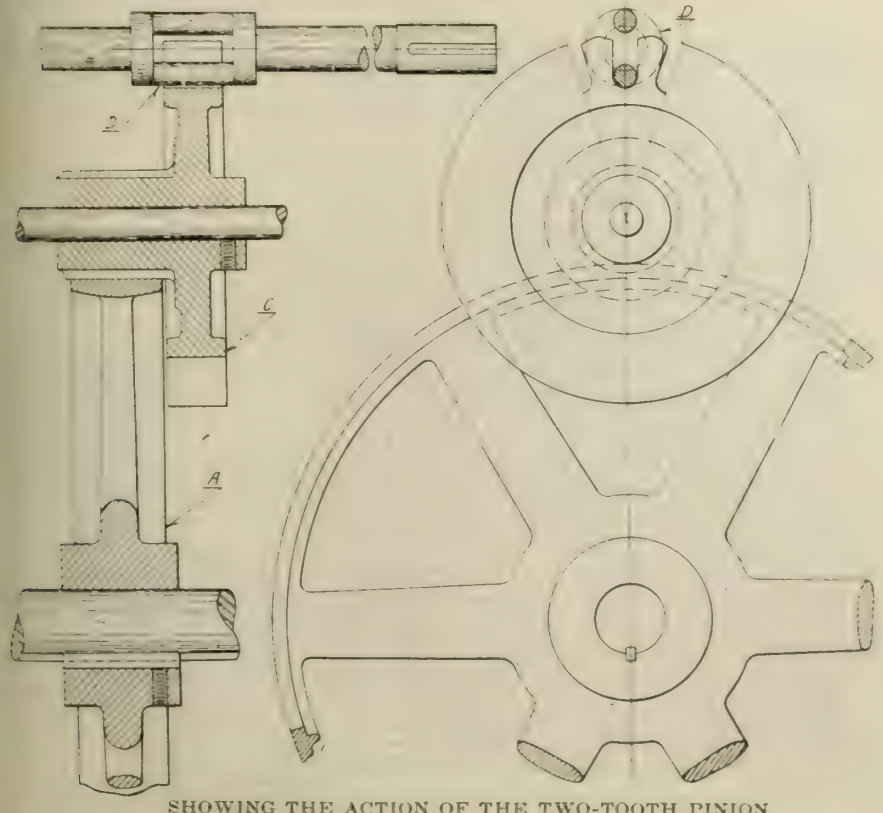
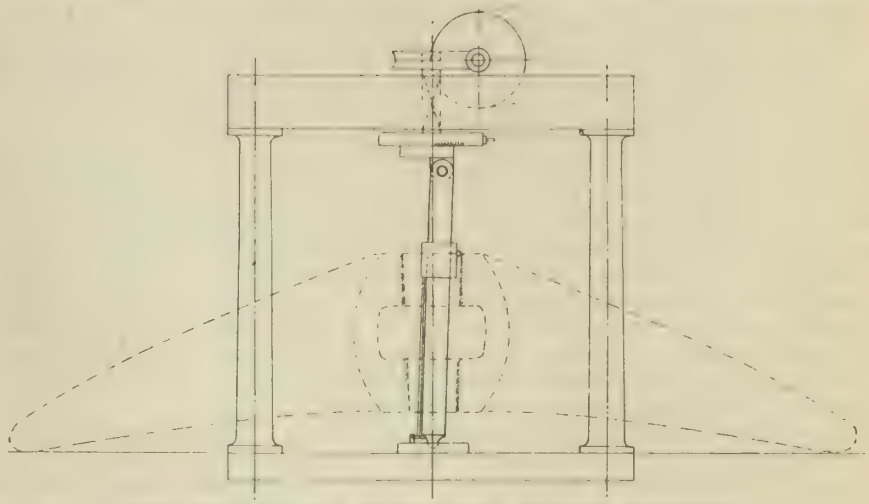
The Building Products and Fuel Co. Saskatoon, Sask., will receive tenders for the erection of metal-clad warehouse estimated to cost $6,000 and also for office building.



# WHAT OUR READERS THINK AND DO



## INTERESTING TWO-TEETH PINION

By G. LAIDLER.

In handling molten metal in large adles it is frequently difficult, owing to he changing centre of gravity of the nass, to maintain the tilt of the ladle by the use of the ordinary gears. With worm gearing this is possible but very difficult when using spur gears. The accompanying sketch illustrates a gear and pinion of interesting design that eliminates the tendency to assume a normal position, and acts as a positive lock when in any position. The large 72-teeth gear A, keyed to the ladle trunnion, is of the usual design, with teeth of shallow depth. The intermediate 13-teeth pinion is integral with the gear C, which has 21 teeth of special shape meshing with the 2-teeth machine-steel pionion D, cut from the solid shaft on which the 18-inch operating hand-wheel is located. It will be seen that for every half-turn of the handwheel the 21-teeth gear is revolved one tooth and the meshing tooth becomes locked between the diametrically opposed teeth of the 2-teeth pinion, thus eliminating the "tangential component" of the ordinary spur gear. This interesting type of gear makes a simple and safe device for holding the ladle at any angle.

SHOWING THE ACTION OF THE TWO-TOOTH PINION.

OUTLINE OF THE PROPELLER BORING MACHINE.

## PROPELLER BORING MACHINE.

By JOHN S. WATTS

In the shop where I served my apprenticeship, we had many large propellors to bore out, and for this purpose we used a machine which was, I believe, a home- made one, at least I have never since come across one at all resembling it.

The accompanying line drawing gives a general idea of its construction, but as it is drawn from memory only, and it is now some twenty years since I last saw it, this sketch is not to be taken as a correct scale drawing. In all these years I have not seen a machine that could compete with the one shown, when all the factors that affect a machine's efficiency are taken into account.

Being a single purpose machine, it is useful only to those shops that have, or can get, sufficient propellor work to pay for its keep, but its first cost is very small, and it will handle the largest propellors quite easily, the only limit being in small propellors having too small a bore to get the boring bar through.

Referring to the drawing, the machine consists of a base plate, to which are bolted a pair of columns, which support the cross beam carrying the driving mechanism. A tight and loose pulley, driven by a belt from the line shaft, forms the drive. On the pulley shaft is a worm, which drives a worm wheel, this wheel being keyed to the vertical shaft.

At the lower end of the vertical shaft is fitted a head, with a carriage which can be slid back and forth by a screw in a manner similar to the cross slide of a lathe.

This carriage has a single eye which takes the top end of the boring bar, the eye connection permitting the bar to be bolted to the carriage, and driven by it, when the bar is at any inclination desired.

The boring bar itself is, in the main, the same as the regular boring bars used for boring out cylinders, having a sliding sleeve to hold the cutting tool, and a screw and star wheel to feed the sleeve along the bar. The lower end of the boring bar is fitted with a ball-shaped end to work in the cup-shaped depression in the base casting, permitting the bar to run when its axis is at an angle the axis of rotation.

The operation of the machine is quite simple. The boring bar being removed, the propellor is lowered into place, and set central over the center in the base, and levelled up. A few clamps are put on the propellor blades, only a few being necessary to prevent a movement of the propellor by the cutting tool.

The boring bar is now dropped through the hole and bolted to the sliding carriage, which is then screwed to the position which will give the bar the inclination corresponding to the desired taper of the bore. To facilitate this the carriage has graduations cut in it for the various tapers in inches per foot length, and can, owing to the greater length of the bar, be set very accurately. Everything is now ready for the tool to commence boring, and it only remains to continue boring out until the diameter at the top is the finished dimension, when we are assured of a good fit.

To face off the ends of the boss, another arm is fitted to the bar, this arm being exactly the same as is used on all boring bars for facing flanges, etc., and requires no description here. The only machine which can compete with this one in facility of handling the work is a horizontal boring machine, which to be large enough to handle sixteen feet diameter propellors would mean a very heavy investment. Further, the boring machine has to revolve the propellor, and to revolve a propellor weighing anywhere up to twelve tons consumes quite an appreciable amount of power. In the machine illustrated herewith, the moving parts are small and light, and the power consumed is very slightly more than that required to do the actual cutting.

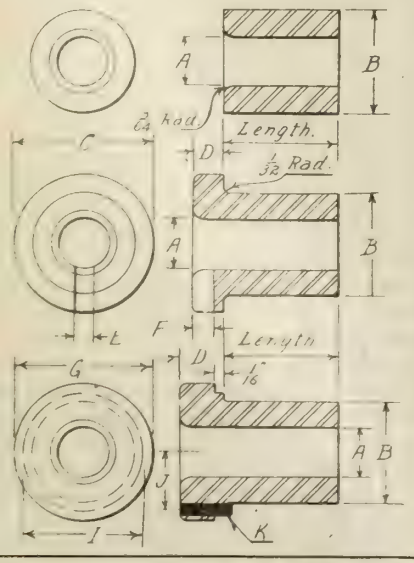
The usual way is to bore the propellor out in a large face plate lathe, which constitutes a very difficult piece of work. The propellor has to be lifted from the floor, where it lies horizontal, into a vertical position, and clamped to the face plate. I know of no more difficult shape to hold in a lathe and the heavy weight makes it dangerous to handle, a job to be entrusted only to the best mechanic available.

To set up a propellor in a lathe will take between ten and twenty hours of a highly paid mechanic and three or four helpers, and will tie up the crane service for a good many hours. This is all avoided in the machine I have described, and even if the machine is used only a few times a year, the saving in cost of operation will soon repay the small capital expenditure.

---

The West Window Regulator Co., has been incorporated with head office at Toronto, and capital stock of $100,000.

## ENGINE PERFORMANCE



In replying to the discussion of his paper on "The Present Position of the Marine Diesel Engine," Mr. James Richardson said, at a meeting of the Institution of Engineers and Shipbuilders in Scotland, that theoretically it should be possible to produce a Diesel engine of small power for approximately 10 pounds weight per brake horse-power developed. The actual weight of the lightest engine as yet constructed is, however, between 50 pounds and 60 pounds per brake horse-power. The highest speed of revolution at which the Diesel engine can be run is an unknown quantity. When, during the shop trials of a high-speed engine the governor broke down, the speed of the engine, which was normally 450, rose to nearly 700, and the engine continued to run for the twenty-four hours necessary to complete the trial, as steadily and as well as at the lower speed. It has been proved, he said, that piston speeds can be increased to 1,400 feet or even 1,500 feet per minute for high-speed engines, without seriously affecting the performance.

## DRILL JIG BUSHINGS.

By F. S.

In the designing of jigs, the proper dimensions of drill bushings is frequently a serious problem. The table shown in the accompanying chart is one not often seen in text books. It will be noted that three different styles of bushings are shown, a plain straight bush, a permanent fixed bush, and a slip bushing. Where these bushings are made in quantities and stocked, the center hole is generally made smaller than the normal size to allow for subsequent grinding to suit the working requirements.

Canadian Machinery

THIS CHART SHOULD BE VERY VALUABLE TO TOOLMAKERS AND DESIGNERS.

# DEVELOPMENTS IN SHOP EQUIPMENT

## ELECTRIC BABBIT HEATER

The Volta Manufacturing Company, Limited, Welland, Ont., have developed and placed on the market an electric furnace for melting babbit and similar metals, which will be known to the trade as the "Ideal electric babbit heater."

This furnace has been in continuous service over a twelve-month period and has been subjected to all sorts of tests which has shown results to the entire satisfaction of the company, who are now putting it on the market.

For commercial purposes it is intended that the current used in heating the furnace shall be taken off the lighting circuit in the plant. To start, all that is necessary is to charge the furnace with the cold metal and turn on the switch. No volatilization of metal occurs as the temperature is such as to eliminate any chance of overheating. Metal can be poured into ladles, or, in the case of valve bearings, the pot can be hung from the hook of a crane, or other appliance, and carried directly to the job, if desired. On account of the heavy heat insulation the molten metal will hold its melting temperature for about two hours, which allows ample time for transportation without chilling of the metal.

Every precaution has been taken to make the furnace simple and convenient, and as near fool-proof as possible. The heating element is of a substantial design and is said to be easily changed. It carries current at a low density, and, on account of the fact that it covers a large surface of the pot, the heat is quickly conducted to the metal.

## DRILL GRINDING MACHINE

The Bellevue Industrial Furnace Co., of Detroit, Mich., have brought out a semi-automatic drill-grinding machine, which is a self-contained unit with the motor located in the pedestal of the machine. The drills are ground on the periphery of the wheel and not on the side, and can be equipped for the grinding of left-hand drills as well as right. Drills with any number of lips can be ground, an index being provided, and no more stock is ground from the drill than is absolutely necessary. The machine is made in two sizes, the maximum drill size handled on either machine being 1½ inches and 3 inches respectively.

DETAIL VIEW OF HEATER, ALSO PHOTOGRAPH SHOWING IT IN OPERATION.

## INSERTED TOOTH FACE CUTTER

The Alfred Herbert, Ltd., Coventry, England, Toronto office at 1-3 Jarvis St., Toronto, are now in a position to supply their patent high duty inserted tooth face cutters in smaller sizes than formerly. The 3, 4 and 5-inch diameter respectively are available, and these cutters are interchangeable on the arbors of the same size solid face cutters to the B. E. S. A.

Since the introduction of this design, the cutters have been supplied for use on all classes of work and materials, and have proved uniformly successful. They are said to be capable of standing up to the heaviest cuts without any movement of the teeth. The latter are fixed in reamed holes and have serrations milled transversely on a flat, being locked in position by a tool-steel bush having similar serrations milled on a tapered flat. In addition to the teeth being held very solidly, they can be removed quickly, and a large amount of adjustment is provided before they have to be discarded.

## IMPORTED FIREPROOF BRICK

A new line of English fireproof building brick now being imported into this country is that manufactured by the Moler Fireproof Brick and Partition Co., an associated firm of Vickers, Limited. This product is burnt brick manufactured from Moler diatomaceous earth, a deposit of marine origin containing sufficient proportion of clay to enable it to be readily converted into plastic form suitable for brickmaking. The raw material is very porous, being able to absorb its own weight of water, and this porosity largely accounts for the lightness, sound-proof and heat insulating qualities of the finished products. It is stated that solid Moler bricks are about half the weight of ordinary bricks, the specific gravity being approximately 0.85. It is claimed that Moler bricks will withstand a crushing load of one ton per square inch. These bricks are particularly suitable for interior work, such as, partition slabs and linings floors, roofs and arches in all classes of buildings. R. S. Griffith, 371 St. James St., Montreal, is the Canadian representative.

# NEW THINGS IN MACHINE TOOLS

### RIVET HEATER

A new electric rivet heater has recently been introduced by the General Electric Company, Schenectady, New York. The heater consists of an air-cooled transformer, with a single turn short-circuited secondary, in which the rivets to be heated form a part of the secondary circuit. The primary winding is designed for operation on 220, 440, or 550 volts, single-phase circuits of 40, 50, or 60 cycles. Tappings are brought out from the primary winding on a drum controller, so that six different voltages can be obtained on the secondary, and the adjustment for various sizes of rivets or rates of heating is obtained simply by setting the handle on the drum controller.

### SELF-CENTERING DRILL HOLDER

A self-centering drill and reamer holder that is intended for use on drilling machines, lathes and screw machines, has been placed on the market by the Woodall-Basch Tool Company of Syracuse, N.Y. The purpose of the device is to grip the drill or the reamer and prevent it from turning, at the same time centering it. The drill is kept in proper alignment by means of a center entering the center in the end. The driving dog which is secured to the drill by means of headless screws, is of the floating variety, being driven by the action of T-slot and bar in the head of the fixture. When used in the drill press the holder revolves with the drill, while it is held stationary when used in a lathe.

### SENSITIVE RADIAL DRILLING MACHINE.

The Crescent Steel Company of Cincinnati, Ohio, are now manufacturing a 2½ foot sensitve radial drilling machine, which is intended for high speed, heavy duty work. The tool is made either with hand or power feed and is geared throughout. Control is by means of a lever and clutch pulley, the machine being belt driven. Six spindle speeds are provided, ranging from 130 to 1,100 r.p.m. The radial arm is supported on steel balls. Radial adjustment of the drilling head is by means of rack and pinion. Similar adjustment, with the addition of a worm and wheel, are provided for the elevation of the table. All gears are of steel, change feed gears running in oil.

### AUTOMATIC CHAMFERING AND THREADING MACHINE

The Grant Manufacturing & Machine Co., of Bridgeport, Conn., have added a new line of double-spindle automatic chamfering and threading machine to their line of machinery. The machine is provided with two cutter spindles, a magazine, a work holder and feeding table. Control of the automatic movements of the machine is by means of a lever located at the front and within easy reach of the operator. Only slight modifications are required for changing the machine for threading both ends of small studs simultaneously. It may also be equipped for the drilling or countersinking both ends of pieces at the one time.

### MULTIPLE-SPINDLE DRILLING HEAD.

To meet the requirements of manufacturers desiring the drilling of a number of small holes closely grouped together in the one piece, John H. Dorman and Son, of West New York, N.J., have developed a special multiple-spindle drilling head, in which the special arrangement of the drill spindles and the driving gears permits of compact construction. The housing is made of aluminum and the main spindle carries, on its lower end, the large gear that drives the intermediate pinions, that in turn mesh with the different gears on the small drilling spindles, these latter gears overlapping owing to the closeness the drill centres. The upper end of spindles are carried in a bronze pla and the thrust bearings are of fibre

### SMALL INDEXING FIXTURE.

M. B. Hill, of 10 Eden street, Worcester, Mass., is placing on the market specially designed indexing fixture use when cutting the squares of hegons on bolts or on the ends of rou stock of any kind. The tool is not tended to replace a more elaborate ture, but it is claimed that it is v serviceable for use in small repair a jobbing shops. The indexing device quite simple, two rows of holes be provided, each in a different plane, where the holes are placed 90 degr apart and the other 60 degrees ap The spring operated locking pin is s contained and there is no danger of l ing any of the parts. It is a very sim matter to change from one setting another.

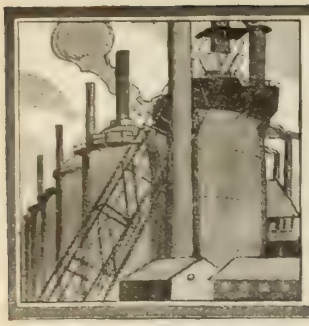
## A Great Labor Leader



THE death of William Crooks in London, England, at the age of 69, marks the passing of a very fine character from the field of the industrial workers organizations. His life is a further proof that character and ability may win out aginst very adverse circumstances, though of course that is not an invariable rule. Crooks was born in one of the worst slum districts in old London, and in 1852, the time of his birth, that was probably the worst in the world. He was forced to commence work at the early age of nine, so it can be imagined what opportunity for education came his way. After doing odd jobs for a time he finally became apprenticed to a cooper, and from then on worked his way forward. After becoming identified with trade unionism, his sterling worth was soon recognized, and his powers of organization were well displayed in the great dock strike, as well as his moderation and absolute dependability. One of the greatest virtues of a gentleman was his, in that his word was binding on him as an oath, and it was said that in the course of his career that word was never broken. He became Mayor of his native borough, then a Guardian of the Poor Law, of which in early days he had been a beneficiary, and finally a member of Parliament. He represented Woolwich, which is by virtue of the arsenal there, a great centre of skilled workmen. His passing will be regretted by employers and workmen alike, for unfortunately his type is rare. If there were more of them, Great Britain would not be in the industrial turmoil that she is in to-day.

## An Interesting Experiment

THE economic situation of the railways of this continent has been causing considerable thought during the last year or two. The U. S. have had their period of Government ownership, with its accompanying muddle and loss, and the Canadian people are more or less cheerfully stumping up to pay the deficits on their railway possessions. Great Britain has also had a period of Government control of railways, and the losses achieved assume very serious proportions. The Government control comes to an end in August next, and Sir Eric Geddes has introduced a bill in the House of Commons which will usher in a new experiment in railway operation. The railways have been granted a sum of practically 300,000,000 dollars to compensate them for losses while under the control of the government, and this sum will be paid in two instalments. In order to put the various lines on a paying basis and bring back the same facilities or something like the same facilites that were enjoyed before the war, the country has been divided into six groups, and all the railways with lines in these different groups are to amalgamate. There will thus be six controlling companies or groups of companies. The various lines will be allowed to arrange their own terms of amalgamation, but if they cannot agree the case will be put before a specially appointed tribunal for adjustment. The groups have been arranged solely with an eye to economic operation and financial position. Provision is made for fixing rates that will bring in a revenue based on that of 1913, with an additional amount that will yield 5% on capital expenditure made while under government control, with other additions to cover capital investments that did not yield interest in the pre-war period. If these fixed rates yield more than the standard aimed at, the excess will be divided between reducing the rates and assisting the revenue of the company. That is, the company will receive 20% of the excess and the balance will be applied to reducing the freight rates. There will be a wage board composed of representatives of the men and the company, and this board will have recourse to a central wage board. The experiment is a far reaching one, but it seems to be based on a common sense viewpoint. There is no doubt that great economies in management are possible under such a scheme, and the resumption of the travelling facilities for which Great Britain was famous before the war will undoubtedly be a help to the general business prosperity of the country. The experiment should be watched with interest by the people of Canada. There is, of course, no parallel between the two situations as far as numbers of roads and density of population is concerned. There is this parallel, however, that Canada, Great Britain, and the United States have all tried a measure of Government control of railways, and two of them have finally handed back the roads to their owners, to the great relief of all parties concerned. Canada seems to be wedded for the present at least to Government ownership of railroads, with all that is incurred therewith. An amalgamation of the railroads of this country under a competent managership in which there was no hint of government control might be the best solution to our difficulties.

## The Signs Are Hopeful

NO less a prophet than Judge Gary has been giving his views recently at the annual meeting of the American Iron and Steel institute, of which he is president. The general trend of the eminent Judge's rmarks was that there was plenty of business ready to be placed, and willingness to place it, if further adjustments were made, leading to lower prices. Judge Gary made the statement that as usual many people would wait too long. There is a good deal in this viewpoint. While there has been a considerable drop in many articles, and in many cases reductions in wages, there is not much chance of any wholesale reduction in the latter item, nor should such a consummation be wished for. Probably in no industry more than in the building industry has the policy of waiting been carried out, especially in this country. While the shortage of homes continues, we are forced into paying exorbitant rents, and to the man who contemplates building a home for himself, it would seem wise to build now and pay the slight extra cost that might be incurred than to continue paying through the nose for the privilege of living in another man's property. If all the prospective home builders who are waiting for further drops in prices were to decide to start in right away, what a difference there would be in the outlook. If on top of this every man who is waiting to place an order for something he wants, but is waiting for a further drop, made up his mind to purchase right away, we should have made the start back to normal times, and be a considerable distance on the road before very long.

# MARKET DEVELOPMENTS

## Buying Continues—But in a Cautious Manner

Business is still placed sparingly, many firms ordering only what they immediately require. There is some talk about the price of steel dropping around August, but nothing definite.

THE market still continues to mark time. Things have not improved, nor are they any worse. The best news from the East is the re-opening of some railroad shops after a ten-day closure, although no assurance of steady work is given. Some dealers claim that good business will come when consumers are in a position to buy in advance of their immediate requirements.

There has been quite an effort in a number of quarters to show that the steel prices developed about the middle of April were being cut, but as some candidly state, "the market is too dull even to allow price cutting." Operations are around 25 per cent., and when a buyer does place an order he wants practically immediate shipment. The order simply goes to a mill that chances to be in operation, and the regular price is charged and paid.

Buyers of steel expect prices to be materially lower in the not distant future, somewhere around August 1st, and while the mills make no effort to controvert the view, they are making no definite statements in this respect.

There has been no change in the Pig Iron market, and one concern purchased 500 tons of basic iron at $23.00 delivered. This would be equivalent to $21.00 Valley furnace. A fair average can be struck around $22.00. Orders however, are only for immediate requirements. Buffalo feels that better business is in sight, the month of May being better than any other months this year. Malleable iron in small tonnage was sold at $24.00.

The scrap metal market is very weak, although some dealers claim they see a chance of improvement. In fact in some quarters it is at present starting to show signs of life. The mills at Cleveland are accepting no shipments of heavy melting steel, while in New York dealers are receiving few calls from brokers with intent to buy.

## RAILROAD SHOPS AGAIN WORKINC. NO ACTUAL PRICE CUTTING EXISTING

Special to CANADIAN MACHINERY

MONTREAL, Que., June 9.—All lines of industrial activity continue to show more or less dullness with general buying on a quiet scale. The local railroad shops are again working after a ten-day closure; but no assurance is given of steady work. Steel merchants very light sales and in small quantities. Orders for single tools and a few small supplies is the extent of the machinery business. Old material is quiet. In all instances price quotations are firm but shading is frequently done to obtain business.

### Some Price Shading.

The local steel situation offers little in the way of feature this week. The light volume of material that is passing into the hands of the consumer makes it difficult for the dealer to figure out the amount of stock he should carry, particularly at a time when the market is so uncertain and when prices are wavering. When speaking of price tendencies and the possibility of cutting to secure business, one dealer remarked that:—"We have heard from some sources that this has been done in the States, but it is our opinion that no actual price cutting is taking place. The quotations generally given at the present time are based on current cost of production plus a reasonable profit on the sale of the material, but it is doubtless true that many producers and dealers are taking advantage of the situation to obtain business, even though a large percentage of the profit is given to the purchaser. On this basis listed quotations must be taken as those that should obtain rather than those actually figuring in a sale." The dealer admitted that price shading was quite common and many believed that small or no profit was better than no business. The situation here may be told in the remark of a dealer. "Buying," he said, "is done in small quantities, and in some cases very small. The movement of plates has shown slight improvement, but other lines are very quiet. We continue to quote 4½ to 5 cents on plates."

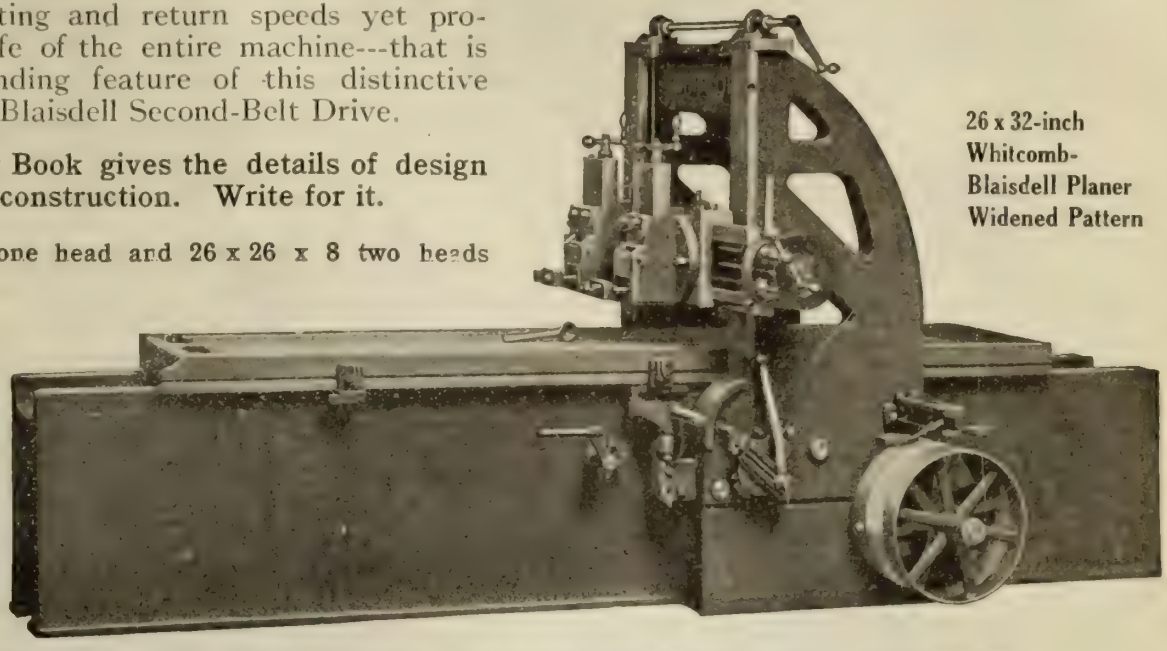
### Slight Signs of Improvement.

Some undercurrents of coming developments in automobile activity in this district has awakened the interest of machine tool dealers, but other than this the movement of equipment has been very light. One dealer stated that a slight betterment might be noted and that he believed that now we were on the return to normal, but it would probably be weeks before any outward sign was noted. "We have turned over a fair volume of business during the past week, but the orders generally are for small quantities and pretty well distributed. This" said the dealer, "gives promise of good business when consumers are in a position to buy in advance of their immediate requirements. Just now we must be content wth the wishes of the purchaser in his conservative needs."

### Some Machinery Scrap Moving.

"Apart from one or two consumers that are regularly taking fair quantities of machinery scrap," stated a dealer here, "the trade generally is very dull, so much so, that at times we can hardly realize that we are in business at all. We are not enthusiastic about taking on more stock, and when material is offered our quotations are so low that the holder refrains from selling the stuff at such figures, retaining it in the hope that a better price will prevail at some advanced date. It would not alter the situation to change quotations, as actual price figures are determined at the time of the sale." Dealers here do not anticipate an early revival of activity.

## MABBINE TOOLS LISTLESS DEMAND FOR RE-CUT FILES



TORONTO.—The slight increase that has been noted in industrial activity during the past week has been taken by some to indicate an improvement in business. This is no doubt true on the face of it, but too much value cannot be placed on a development of this character, as it is not difficult to see that some lines of activity cannot be carried on successfully unless continuous operation is carried on. This is particularly true in relation to steel production, the volume of certain sizes of steel determining to a large extent, the duration of the operating period of the mill. While nothing definite can be said on any market under existing circumstances, the optimism expressed by some machine tool dealers gives slight cause for encouragement.

### Steel Movement Light.

The reopening of a number of shops in this district has given a tone of optimism to the industrial situaton, but while improvement has been reported in some lines, the volume is so light that it is difficult to determine whether this current activity is more than the dissemination of accumulated orders. It is true that some plants have been operating additional hours but it is stated that this has resulted from business that has been coming in, and which it has been unprofitable to produce in small quantities. The steel market still reflects the conservative attitude that has dominated the buying market for many months. "At the present time," stated one dealer here, "it is a very rare thing to get orders running into tonnage. The usual practice is for the consumer to buy just what he absolutely needs for the day, or at most the current week. We had an order the other day for five light sheets of steel from one of the largest manufacturers in the country, and by the instructions issued with the placing or the order one would think they were taking on considerable tonnage." While in this office this week we heard an order come in over the phone for a piece of sheet 6 ft. long by 6 inches wide, by ⅛ inch thick, to be delivered. The cost of the material was little more than it would cost to deliver it, so one can readily see where some of the profit goes in selling steel. "There is little or no change in the situation," said the dealer, "prices as quoted are in keeping with costs plus profit, but prices are by no means fixed when sales are actually made. Few dealers are letting business go by when a little shading will clinch the sale. The profits are cut but the sale results in added turnover." One distressing feature just now, incidental to small orders, is the relative percentage of increase in overhead when compared with business carried.

### Second Hand Sales Maintained.

The week has been a listless one in machine tool circles. What little business is being done is largely confined to trading in used equipment. "It has been our experience," said a tool dealer, "that users of machinery and supplies are not buying equipment when they are able to utilize available machinery, taking from one department to build up another. When it is necessary to acquire machinery, the usual practice is to look around for second hand tools that will fill the bill, and even then they endeavor to secure the very lowest price before the sale is closed." One promising condition that will eventually react to the benefit of business generally is the cleaning up process that many jobbing houses and machinery dealers are carrying out. The representative of a large engineering supply house, that has branches across the Dominion, has been conducting a policy of interorganized co-operation in liquidating their entire stock. Speaking on this subject the dealer said: "For many months now we have concentrated on the problem of reducing stock to the minimum without actually running ourselves short. By this we mean that all the branches are considered collectively and where a surplus of a certain line is carried at one branch all orders for that particular line are forwarded and shipment made from the stock on hand. When a line is getting low we secure new supplies and distribute among the various centers according to the estimated demand. In every way we are getting stocks down to the lowest possible working basis."

One small tool dealer here has found that there is a good demand for recut files and he has opened a small plant in Toronto for this purpose and reports good business. This dealer stated that turnover for the past several months has been quite steady but below normal.

### Scrap Still Dull.

It would be difficult to make a statement that would differ from those of previous weeks in regard to old materials. The market is virtually stagnant, just sufficient moving to make dealers realize that they are still in business. Prices on all lines are unchanged and nominal.

## POINTS IN WEEK'S MARKETING NOTES

**Points in Week's Marketing Notes.**

**The Boston market reports a slight improvement in the demand for cast scrap, while Pittsburgh claims that interest on the part of melters is again at low ebb.**

—

**Dealers in New York are receiving few calls from brokers with intent to buy. In Buffalo the only activity is the efforts of a few dealers to buy heavy melting steel at a price that will enable them to turn it over for $13.**

—

**There is no visible change in the Pig Iron market at Pittsburgh. Some of the merchant producers express the belief that prices will not go much lower in the immediate future.**

—

**Salesmen covering the New England territory within the past few days report that foundries are operating at about 20 per cent. of capacity, and many of them are well supplied with pig iron and do not expect to be in the market for months.**

—

**The feeling on the Buffalo market is that better business in Pig Iron is in sight. The same market at Philadelphia is weak with irregularity in prices. The sales in pig iron at Cleveland have been light and the market weak.**

—

**Pittsburgh reports that practically all buyers of steel expect prices to be materially lower in the not distant future. Aug. 1st is quoted in some cases. The mills make no effort to controvert this view, though of course they do not definitely predict that prices will be lower.**

## Scrap Metal Markets

BOSTON reports that the demand for cast scrap continues to show a slight improvement although prices in many cases show softness. During the week an eastern Massachusetts consumer bought 300 tons of a special grade of No. 1 machinery scrap at $22 delivered. Another consumer bought two cars at $18.50 delivered and these two sales probably represent the range of the present market. Small dealers watching declining pig iron prices are more inclined to dispose of their stocks than they were heretofore.

Interest in the Pittsburgh market on the part of melters again is at a low ebb and this find reflection in a slightly weaker undertone. There has been no change in prices of the heavier lines of open-hearth grades, but dealers are finding some difficulty in obtaining recent prices on such material as turnings and borings. One Pittsburgh district steel company claims to have bought fair sized tonnages of machine shop turnings the past week at $8.25 and is offering that price on such lots of this grade as are being offered.

At New York an indication of dullness is the fact that dealers are receiving but few calls from brokers with intent to buy. Three Eastern Pennsylvania mills are buying small quantities of heavy melting steel, paying no more than the equivalent of $7.50 New York.

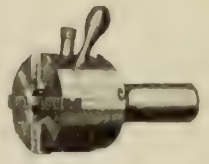
Some of the dealers on the Cincinnati market report the market is picking up slightly. There have been some small inquiries for heavy melting steel and prices are being firmly held. A pipe company in this district was in the market last week for a small tonnage of cast scrap. Local foundries are not showing much interest.

At Buffalo the only activity is in the efforts of a few dealers to buy heavy melting steel at a price which will enable them to turn it over for $13. This is difficult as the $13 price is firm.

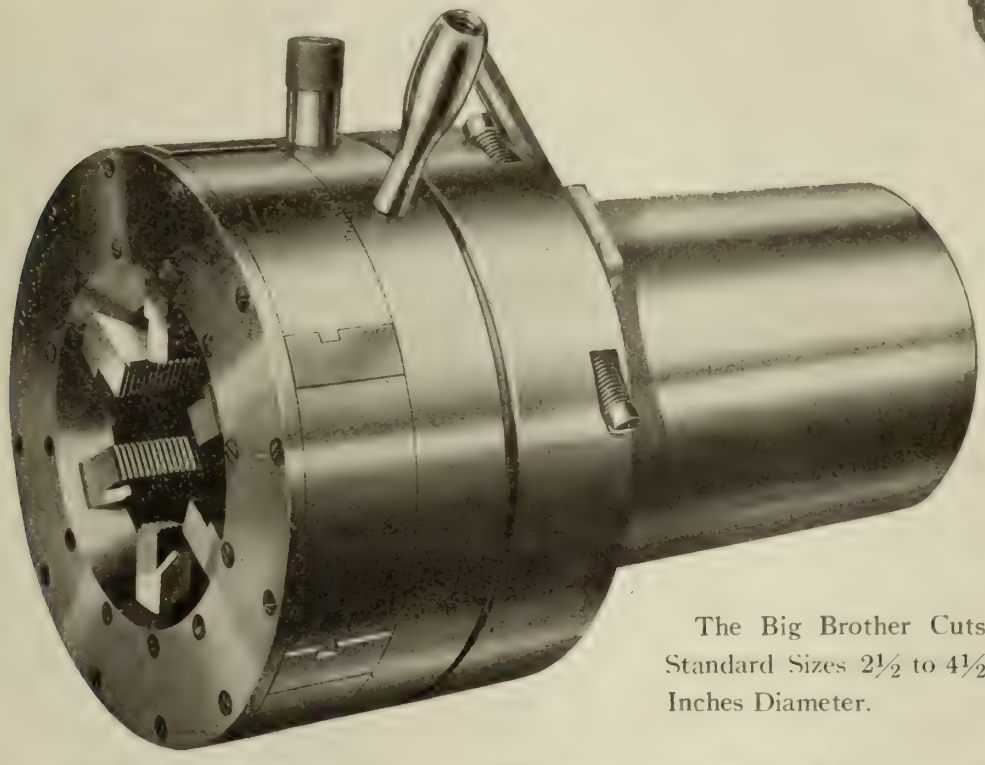
Cleveland market reports that prices are weaker on cast iron borings, mixed borings and short turnings now that the local consumer who recently purchased considerable scrap in these grades is out of the market. Dealers who have been paying $8.25 for these grades are now offering only $7.50 to $8. Local mills are accepting no shipments of heavy melting steel.

## Pig Iron Markets

THERE has been no visible change on the pig iron market at Pittsburgh during the past week. Business is very limited and very few inquiries are on the market. It has been reported that the West Penn. Steel Co. has bought 500 tons of basic iron at $23 delivered. This would be equivalent to about $21, Valley Furnace, as the freight from the Valley district to Brackenridge, Pa., is $1.96. Some of the merchant producers express the belief that prices will not go much lower in the immediate future because the position of the market at least as far as stocks of foundry are concerned, is much stronger than it was a few weeks ago.



New York reports that the largest inquiry reporter is for 1,200 tons, half No. 2 plain and half No. 1, which comes from a New Jersey melter. Salesmen covering the New England territory within the past few days, report that foundries are operating at about 20 per cent. of capacity and many of them are well supplied with pig iron and do not expect to be in the market for months.



The past week has been very dull in the Birmingham district. Lots of 500 and 100 tons by different makers for Southern delivery were sold at $22.50.

Williams & Wilson, Ltd., Montreal. The A. R. Machinery Co., Ltd., Toronto, St. John, N. B., Halifax, N. S.

Real tonnage can be placed at $22. Inquiry is much more brisk. Additional foundries find themselves out of iron, but order only what is needed now. The rate on pig iron has been reduced from $1 to 90c, on billets, from $1.50 to $1.05 and on cast iron pipe, from $1.50 to $1.05 in minimum lots of 60 000 pounds, and $1.25 on minimum lots of $40,000 pounds.

The demand for pig iron at St. Louis has shown no particular change during the past week and there has been no improvement in the tone or quotations. Sales and melting are at a very low ebb and while the distant future is regarded hopefully, the immediate present is still of the hesitant character that has prevailed in the market for many months. While No. 2 Southern may be regarded now as practically on a basis of $22 per ton for 1.75 to 2.25 silicon, it is not selling in competition at this point with the Northern and local irons.

The feeling on the Buffalo market, is that better business is in sight. Two interests find shipping on old contracts considerably better and the month of May will show a greater tonnage on old contracts than any months this year. One producer has in his hands an export inquiry of 1,500 tons of foundry iron, but it is not expected the order will be placed there, the belief being that some foreign furnace will get the business. A small tonnage of malleable was sold for $24. One furnace finds increasing activity with small foundries which have lately resumed.

Boston states that New Sloss-Sheffield Alabama prices are announced with silicon 1.75 to 2.25 at $22.50 furnace and 50c differentials on each higher silicon content. No sales are reported at the new schedule nor has Buffalo iron sold since last reports.

The market at Philadelphia is weak with irregularity in prices. $23 furnace has been done on No. 2 plain iron on shipments bearing a high freight rate, whereas $24 furnace would be quoted on shipments into this immediate district. Some consumers have stated that they can buy eastern Pennsylvania No. 2 plain iron for $22 furnace, but no sales are reported on this basis. There is nothing to test the price of basic iron, but it is intimated that fair sized inquiry would find furnaces willing to sell at $24 furnace.

At Cleveland the sales in pig iron have been light and the market weak. Orders for foundry iron placed during the week were mostly at $23 for No. 2 and higher quotations have about disappeared. An inquiry from the American Radiator Co. for 350 tons of foundry iron for its Springfield, Ohio, plant brought out a quotation below $23, the low price evidently not having been named by a lake furnace. Locally there is no demand for foundry iron and local prices have declined 50c.

# BUYERS WANT IMMEDIATE SHIPMENT ARE STEEL PRICES TO BE LOWERED?

PITTSBURGH, June 9.—Each week the steel market gives a fresh exhibition of how dull it can be. All conceivable limits have already been transgressed. Some of the large steel interests report that they are in receipt of practically no inquiry at all. Some sales of course are being made, but they are in unprecendentedly small quantities, carload order predominating. This is the case quite generally with the independents. The Steel Corporation may be receiving a slightly larger proportion than the independents, in new orders, but this is quite doubtful. Apart from new business, the Steel Corporation has its large volume of contract business with regular customers, on which there is always some specifying, but the specifications are very small. In many cases the contracts now in force are contracts that were made originally to be completed by the end of last year. The corporation could not make full deliveries last year, its operations being restricted by railroad conditions, and the tonnage held over to this year has not all been worked out yet.

In other cases some fresh contracts were made for this year, and they are largely to be specified still. Last January the condition with a number of Steel Corporation customers was that they had contracts which in normal times would give them their needed tonnage to July 1, while at their then rate of consumption the contracts would take care of their requirements through the whole year. In present conditions the contracts will last longer still. The condition can be seen from the corporation's reports of unfilled obligations, which amounted May 1 to 5,845,224 tons.

The figure for June 1, not yet announced, will be about 5,500,000 tons. The corporation's capacity, in steel products for sale, is about 52,500 tons a day, and the present outlook is that the corporation's rate of operation for a few weeks will not be over about 35 per cent., which would give it shipments of 18,400 tons a day. At this rate it would require 300 working days to equal 5,500,000 tons, or practically a whole year.

As previously reported, the steel mills all told, corporation and independent, operated at 30 or 31 per cent. in April. The May average was less. If operations are not already down to a 25 per cent. rate they will be very shortly, and according to the present outlook the average for June and July will be under 25 per cent. July being always a particularly dull month in the steel market, and orders being extremely light already, no increase in operation can reasonably be expected this side of August.

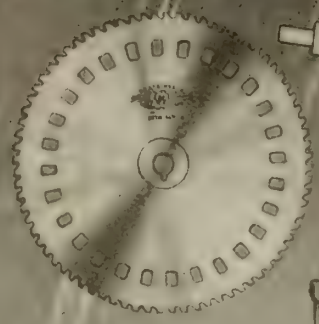
### Prices.

In the past few weeks there has been quite an effort in a number of quarters to show that the steel prices developed about the middle of April were being cut. This effect was due to theory rather than actual experience. The market was dull, hence it was assumed that prices ought to be cut, therefore were being cut. The fact is that the market is duller than that. It is too dull for price cutting. With operations as a whole around 25 per cent., and with the corporation operating at a higher rate than the independents, and not cutting prices, the position of the average independent mill is that it is closed. Orders when offered at all are for carload lots. Is a mill going to cut the price on a carload order and then go to the expense of starting a department to fill a carload order? When the buyer does take hold he wants practically immediate shipment and will not wait for a mill to start next week or week after. The order simply goes to a mill that chances to be in operation, and the regular price is charg and paid.

Undoubtedly there is price cutting some lines, where occasionally an or much larger than a carload is to placed. Such cutting is not uncomm even in an apparently strong market. is the rule rather than the exception line pipe, for ir . Another c is that of tin plate. It has been m or less of a trade practice to shade regular market price on odd lots out mill stocks. Just now some of the m have large stocks and of course they disposed to make the usual or a grea concession on sales out of stock, if buyer can use the particular size av able.

It appears that practically all buy of steel expect prices to be materia lower in the not distant future, say about August 1. The mills make effort to controvert that view, thou of course they do not definitely pred that prices will be lower. The ch questions are when, by what procedu and by how much, will prices decli As to the method of procedure, at beginning of last February the in pendents began cutting the Steel C poration prices and the corporation the thing go on for over two mont Other things being equal, the same thi might occur again, but there is defin information that the corporation wo not at this time wink at price cutti by independents, and that as a mat of fact the independents have been formed as to this attitude. If they prices the corporation will follow the If the independents do not, then th will be a general cut all at once, not the very near future but probably tween August 1 and September 1.

As to the extent of the decline seems like a fair guess that it will erage about $10 per ton in the differ products. This guess is not based any inside information and it is not mere stab in the dark, but is based u proportions to pre-war prices, as f lows: A weighted average of all important finished steel products sho that the average in the ten years bef the war, 1904 to 1913 inclusive, v $36 per net ton. The war control pri averaged about $76 a ton, or $40 mo The reduction in December, 1918, v about $4 a ton, while the Industr Board reduction of March 21, 1918, v about $7, and the reduction past A from Industrial Board prices avera about $6. Thus the total decline fr war control prices has been about $1 ton, leaving the average to-day ab $59. That is 60 per cent. above the p war average.



To cut this in half, to 32 per ce would make the average $47.50, about $11.50 decline from the prices veloped last April. It seems altoget improbable that the mills could or wo go much farther than that, consider the higher wages and freights and fact that they cannot get an economi operation at best because there is hope within the next few months of ting even a 75 per cent. operation e if the steel was given away. On other hand, the mills want to stimul business and to cut less than $10 a would probably cause buyers simply fold their arms to wait for "the n cut."

# TO ADVERTISERS, AND SUBSCRIBERS

It is common knowledge that the union printers in many towns and cities in Canada and the United States are on strike. For the first time in its 35 years history The MacLean Publishing Company is involved and we believe you will be interested in receiving a statement as to what the printer's unions are striking for and why their demands cannot be granted.

A year ago (although the wage agreement at that time had over a year to run) the Toronto Publishers and Master Printers gave their employees voluntarily a 10% advance in wages, making the minimum wage $35.20 for a 48-hour week. This was given in recognition of the fact that living costs were then advancing. This voluntary agreement for $35.20 a week expired June 1st. Notwithstanding that the cost of living has declined 22% since March 1920, the printers' union demanded a 44 Hour week and a wage of $44.00. This means four hours per week less work and an increase in rate of pay per hour of over 33%. Employing printers can grant neither shorter hours nor higher wages and the saner printers realize that their union's demands are unreasonable. A large percentage of our own men did not want a strike, but the union leaders in the United States have ordered it and the strike is on.

Negotiations have been carried on for months. The employing printers have been tireless in their efforts to bring about a settlement without a strike. They are now engaged in a fight, not only for their existence but for a principle in which every business man is interested. If the unions secure their unreasonable demands then the fight would surely be carried to other industries. Business men with whom we have discussed the matter have been most emphatic in urging us to take a most determined stand. "Stay with it and we'll stand with you", they say.

And so we shall "carry on". We shall be somewhat handicapped, especially at first there may be occasions when you can extend your co-operation and support and we feel that we can count on you. It is our intention to issue our publications regularly and as promptly as possible. There will be difficulties to be overcome, and for a short term our service may not be up to its usual high standard. If, therefore, your publication does not reach you on time, if we have to repeat a former advertisement, if proofs are not submitted, or if we fall short of full efficiency in any way, we ask your kind indulgence. We are fighting for greater efficiency at a critical juncture in the world's history, and your co-operation and moral support will help.

# INDUSTRIAL NEWS

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

## INVENTORS MAY AT LAST GET A CHANCE TO PROVE THEMSELVE

THE patent offices at Ottawa, Washington and other capitals of the world are stacked with models of inventions, which represent the ambitious, but usually disappointed hopes of thousands of people who were ready to revolutionize industry and incidentally make a fortune for themselves. Some of them deserved well and made good, others have been the bas's of sales of stock on an unbusinesslike basis, which never brought results. The relation between the inventor and the public is chaotic and it often leads to great waste of money by investors who are led into supportin; a project regarding which they have insufficient information. These conditions has led to the proposal that the ideas of the dreamy inventor shou have a better method of testing out, that the world in general may deri the proper benefits from new ideas. has been suggested that a Developme Corporation be formed, which should semi-public in its ownership and contr The stockholders might include the Ir and Steel Institute, the Federation Construction Industries, American E gineering Council, National Electr Light Association, the textile associ tions, and many others of organiz groups. The use of the larger technic schools might be secured for laborato purposes, and model shops, and it shou not take much further expense to te out inventions in a practical way.

## TRADE GOSSIP

The Toronto Asphalt Roofing Mfg. Co., Ltd., who are building a new factory at Mount Denis, state that they expect to install machinery about the end of June. From present outlook actual production will be started some time in August, when they will manufacture a complete line of roofing materials, including slate, roll, etc. The plant being erected is of steel, brick and concrete construction and will be modern in every respect.

The Bell Asbestos Co., Thedford Mines, Que., has dismissed 40 of its employees in the mines and has cut the wages of the rest by from 75 cents to $1.25 a day. No work is being done on Saturdays.

After a strike lasting since May 1st, the 100 employees in the stone-cutting trade in Montreal have accepted the scale of wages offered them last March. Rates agreed are 75 cents an hour for stone-cutters and 60 cents an hour for machine operators, to be in force until May, 1922.

The Local Hydro-Electric Commission, Walkerville, Ont., are planning to erect a modern office building and store.

The Brown Wigle Woollen Mills, at Kingsville, Ont., were destroyed by fire recently.

The Kemp Metal Auto Wheel Co., Ltd., has been incorporated with a capital stock of $1,000,000 and head office at Toronto, to manufacture automobile and metal wheels, machinery, metal goods, etc.

The Dominion Steel Plant, Sydney, N.S., have announced a wage reduction, taking place on June 5th. On the same date, the plant are commencing a 40,000 ton rail order for the C. N. R.
2-column head

The Canadian Edison Appliance C Ltd., Stratford, will have about $30,0 worth of die work to give out duri the year and desires to get in touch wi firms who can handle this kind of wor Edison, Hotpoint and Hughes lines electric goods are manufactured.

The Canadian Locomotive Co., Kin ston, Ont., has closed its works as had no orders on its books. The co pany intend, however, to begin imme ately the erection of an addition to plant which will cost approximate $110,000, to provide greater faciliti for handling material and future bu ness.

### NEW PLANT NOW OPERATING.

The Walker Twist Drill & Tool C Ltd., Walkerville, Ont., have purchas the plant, equipment, stock, and all u filled orders of the Welt Twist Drill C of Canada.

The products of the new organizati are known as the Walker brand, a under the new company, a modern pla is now in operation on high standa drills, reamers, cutters, and special to in carbon and high speed steels.

### VARIED LINES.

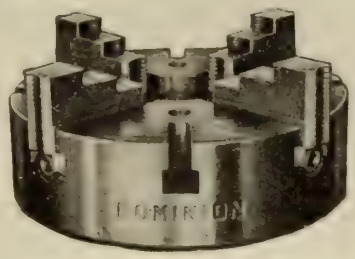
The Eclipse Counterbore Co., Lt Walkerville, Ont., have issued th catalogue No. 9, this book containi a full description of their varied line taper shank holders; adjustable s collar holders; safety holders; adju able length holders; counterbore c ters; countersinks; combined core dr and facers; pilots; interchangea drills; inverted counterbores; and s cial tools.

The Providence Engineering Co Providence, R. I., have forwarded various circulars on their lines of corp ball bearing drilling machines. T circulars are well illustrated, and f specifications are given.

### BOOK ON BRASS ROD.

The Bridgeport Brass Co., Bridgeport Conn., have issued an interesting book on the manufacture of brass rod for use in screw machines, with particular reference to certain improvements which they have originated. This book, which consists of 16 pages, makes very interesting and instructive reading.

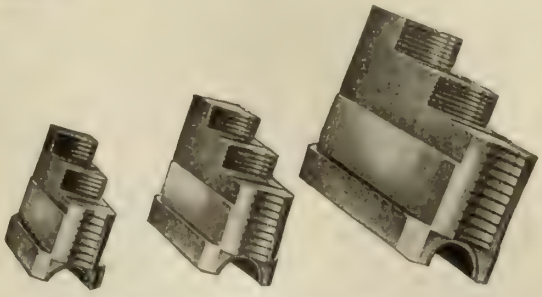
### FLEXIBLE SHAFT BOOK.



The Herzi Mfg. Co., Bridgeport, Conn., have sent us a catalogue which describes their line of flexible shaft equipment. Numerous photographs of installations and uses are shown, together with detail of the different equipment.

### VARIED MACHINE TOOLS.

The Selson Engineering Co., Ltd., London, England, have forwarded us their catalogue, No. 103, which contains details of various of their lines, these including screw cutting lathes; brass turners' lathes; shaping machines; radial drilling machines; mitreing and slotting machines; tool grinding machines; high speed metal saws, and other allied lines. Specifications and descriptions are given in each case, and the catalogue is well illustrated throughout its 8 pages.



### GRINDER BOOK.

The Grand Rapids Grinding Machine Co., Grand Rapids, Mich., have issued a grinder book that discusses and illustrates various styles of their grinders. Helpful hints regarding the care and use of twist drills is also included, together with details of the machines they make for grinding such drills. Tap grinders conclude this interesting book.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

The Jaws Are Extra Strong

THEY are drop forgings, made of best quality steel, heat-treated and hardened. The threaded portion of jaws form a half nut for the setting-up screws. Have stood the test of heavy duty work in our own shops where accuracy was the only accepted standard.

## MOTORS WANTED

WANTED—ONE 10 H.P., 3 PHASE, 25 CYCLE, 220 volts; one 25 h.p., 3 phase, 25-cycle, 220 volts. Complete with low voltage release starter, base and pulley. Box 781J, Canadian Machinery.

## SALESMAN WANTED

WANTED — BY WELL-KNOWN AMERICAN manufacturers of pneumatic tools enterprising salesman for Canadian field. Reply giving full experience, present connection, etc. All replies will be treated in confidence. Box 782N, Canadian Machinery.

## MACHINE WORK WANTED

MACHINE WORK WANTED FOR LATHES, shapers, milling machine and planer, etc. Hourly or contract basis. Prompt delivery. W. H. Sumbling Machinery Co., Toronto. (etfm)

## POSITION WANTED

UP-TO-DATE MACHINE SHOP FOREMAN desires change, as foreman, general foreman or superintendent. Age 37. Apply Box 783, Canadian Machinery.

## MACHINE WORK WANTED

We are equipped to handle all kinds of general or special machine work. All operations in our plant are done under the most careful supervision and we can satisfy you as to price. Always available for consultation.

**PERFECT MACHINE COMPANY, GALT**

Builders of Reliable Machinery.

## DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

### MACHINE TOOLS AND METAL WORKING EQUIPMENT

# United States Electric Drills and Grinders

## The "BUZ"

For all kinds of general drilling in metal up to 5/16"—name plates, cotter pin holes, oil holes, etc.

The "BUZ" is especially adapted to corner drilling—drills within ¾" of corner. Switch is located in handle; under absolute control at all times. Attaches to any lamp socket, alternating or direct current, 110 or 220 volts. Guaranteed the most powerful electric drill of its weight on the market.

Order a few to-day for trial. Their time and labor saving ability will convince you you need more!

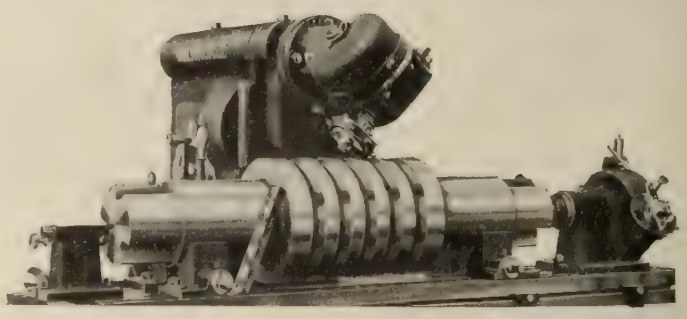
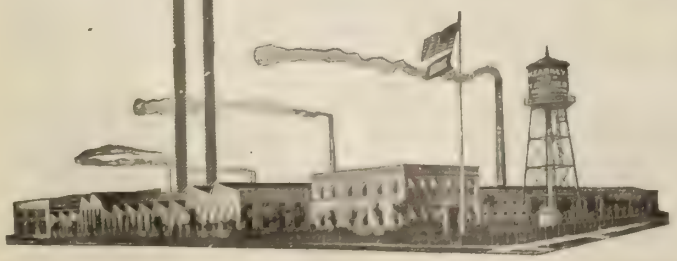
# MILWAUKEE MILLING MACHINES



## Efficient on Light and Heavy Milling



Heavy milling jobs are not unknown to Milwaukee Universal Milling Machines, while delicate and intricate ones are efficiently performed with little effort.

Both light and heavy milling operations are handled with such smoothness and accuracy that the finest results are obtained. Because Milwaukee Universal Milling Machines perform such a wide variety of work, they are particularly well adapted for the tool-room.

The jobs shown in the two illustrations are representative of "Milwaukee" adaptability. The upper illustration shows a jig being bored with a fly cutter. The lower illustrates the milling of a chilled roll with the use of a Universal Milling Attachment.

**You can't help noticing the good qualities of**

## Pratt & Whitney Taps

Their free cutting qualities, their extreme accuracy and their extraordinary ability to outlive others distinguish them.

The con-eccentric relief—a distinctive P & W feature—is the secret of their goodness. One-third of the cutting edge is concentric. The remaining two-thirds has eccentric relief. Taps can be sharpened at the only correct point—on the face of the cutting edge. Sharpening in no way effects their size.

Yes, they cost a little more than some others, but they're well worth the difference. Carried in stock as are all other P & W Small Tools at our sales offices and agencies as listed.

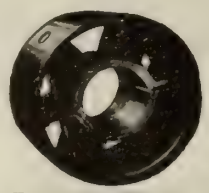
# DODGE

## A pulley for every purpose

There is a specific place for every type of pulley; two different types will not render the same service in the same installation. To this, however, not everyone will agree.

While Dodge is at all times ready to give without prejudice an opinion as to the pulley best suited for any purpose, the fact that that opinion will not always be accepted is not lost sight of. Because of it the Dodge line has been extended to include every type of practical pulley.

Dodge "Independence" Wood Split; Iron Center Wood Rim; "Standard" Iron Split; Keystone and Oneida Steel Split; they are all Dodge-built, Dodge-guaranteed and Dodge-spirited.



Whatever your opinion as to type, be sure it was built by Dodge.

# One Hour *or* Ten Minutes

## *Which Do You Prefer?*

By actual time study in one foundry it was found that an 8′ x 6′ x 6″ cope requiring one hour to tamp by hand could be rammed and peined in ten minutes with a Little David Sand Rammer and the results were better.

When Little Davids are used castings never swell, pin holes are unknown, and no matter who uses them, they deliver blows of just the right weight, thirteen times faster than the best hand tamper. They are moderate in first cost, require very little power, practically no repairs, and never tire or "soldier on the job."

Equally valuable in foundries, large and small, they are a real factor in increasing production and lowering costs.

Bulletin 8000 describes them and other Little David labor savers. Write for it.

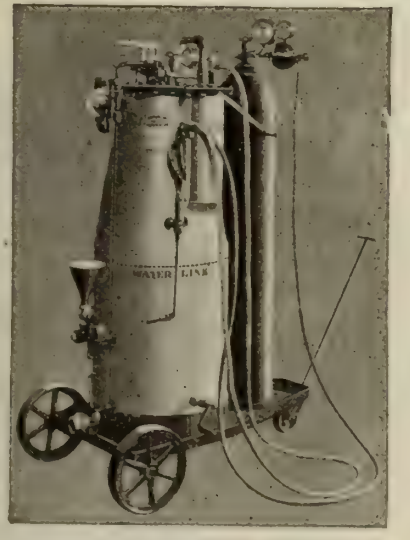
# Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

## Walton it Out in a Jiffy

And save the casting.



Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

**Sixty-day trial offer** proves the Walton Extractor pays for itself.

Write.

**The Walton Co.**

Hartford, Conn.

This is the Imperial Acetylene Generator which can be used with any make of welding apparatus—saves from 2c to 4c on every cubic foot of acetylene gas used in welding. It can be mounted on a truck with an oxygen tank and easily transported anywhere in the plant.

# An Imperial Welding Outfit Will Save You Hundreds of Dollars

Factory and production managers are just beginning to learn that oxy-acetylene welding is one of the most useful and economical processes which they can use. In minutes and hours, instead of days and weeks, broken pulleys, gears and machine parts can be made good as new.

Not only is there a saving on repair parts, but production is speeded up, departments are kept working and layoffs are avoided.

## Imperial Automatic ACETYLENE GENERATOR

In many factories, short cuts on production are made with oxy-acetylene welding, with considerable saving on costs. The whole subject of welding is worthy of your investigation. Write for our catalog and description of welding possibilities.

**Send us the name of your distributor through whom you prefer to deal.**

# IMPERIAL BRASS PRODUCTS

# THE JOHNSON FRICTION CLUTCH

## The Case Against the Countershaft

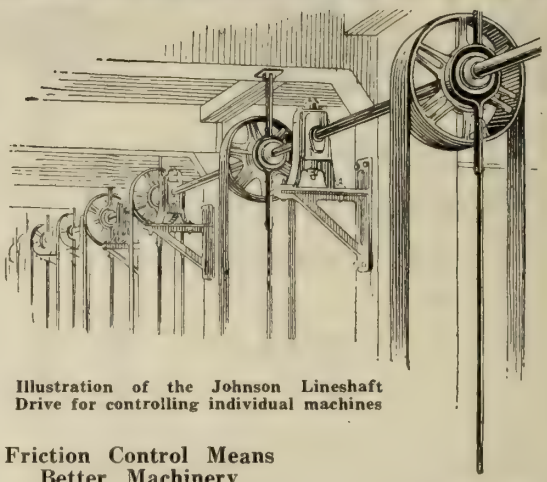
The old familiar countershaft drive, through cross belts and tight and loose pulleys, stands accused of the following offences against efficiency:

1. Involves needless equipment.
2. Costs too much to set up.
3. Prevents economical and systematic use of space.
4. Operates sluggishly.
5. Multiplies belt troubles and the resultant cost of upkeep.

**Modern practice has discarded the antiquated countershaft for the simplicity and efficiency of the clutch drive direct from lineshaft.**

### Adopt the Johnson Lineshaft Drive

The economical, efficient and durable method of power transmission through friction control.



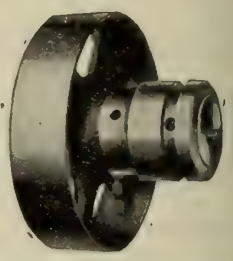


Illustration of the Johnson Lineshaft Drive for controlling individual machines

**Friction Control Means Better Machinery**

# KEMPSMITH

## No. 2 UNIVERSAL

Thirty-two years ago the Kempsmith Company began its career in a small one-story frame building. To-day there are four main buildings, aggregating 106,000 square feet of floor area, besides various storage sheds, etc. Every building of the plant is a model of its kind.

It has always been, and will continue to be, the purpose of the Kempsmith Company to produce machines of the highest quality only, suited to the most advanced practice.

Every machine, whatever size or type, is put to test under cuts and conditions purposely more severe than it will encounter in even the most progressive shops and when it leaves our factory it has our positive and definite guarantee back of it.

***Literature will be gladly sent upon request***

SKF

# Buy Chain by the Pound of *Strength* and *Service*

TWO chains may be identical in appearance, yet one is ten per cent heavier and thirty per cent stronger than the other. Mere inspection can tell little; the use of a scale and a few simple tests will reveal marked differences.

If you lack facilities, a simple bending test with the aid of a vise and a hand hammer will tell you something. Don't buy a chain that breaks short under the hammer, for you want a tough, not a brittle chain.

Subject our chains to the most thorough comparative tests and you will find substantiation of our claim that we give you more pounds of service and units of durability than any other maker. And what is more important, forty years of experience as chain makers have taught us how to maintain the high standards.

We have chains for every type of transmission, elevator or conveyor, and have engineers to assist you in making proper selections.

Write for catalog containing prices and full particulars.

# Have You the Tools for Making This Headstock Spindle?

Making headstock spindle for Rivett No. 106 Automatic Internal Grinder, Rivett Lathe and Grinder Company, Boston, Mass.

*Starrett Tools needed for this job are: Starrett 2" Micrometers, 6" Outside Calipers, 12" Scale, 6" Hermaphrodite Calipers, and a Bevel Protractor.*

Starrett Tools afford that dependable gage of accuracy essential to the proper machining and finishing of Rivett Internal Grinder headstock spindles.

For every metal working operation where the work must be finished within close limits, Starrett Tools afford a positive check on accurate work.

Picture yourself on this spindle job. Have you the Starrett Tools necessary for handling it right? Be ready for any job. Overhaul your Starrett Tool kit now, and make it complete. Write for the Starrett Catalog No. 22-3 Free on request.

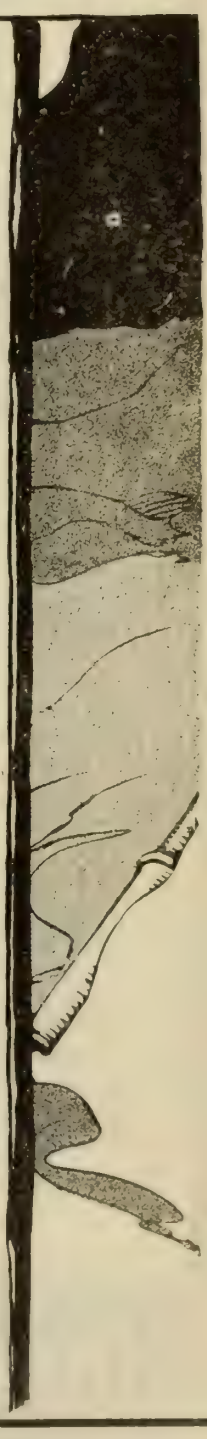
# You Can't Row a Boat with One Oar

An unbalanced advertising campaign, like a one-oar boat, never gets anywhere.

Sound copy must be balanced by scientific space selection. Mediums deserve as much attention as merchandising.

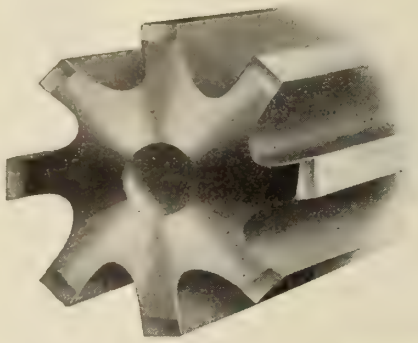


To buy space scientifically circulation must be *analyzed*—not merely counted.

Do you ask of a publication not only "How much?" but also "How did you get it?" and "Where does it go?" If you fail in these particulars you are trying to make an advertising campaign go with only one oar.

The answers to these questions can be obtained by studying the A. B. C. reports. To read the circulation figures only is not enough, even though they are verified by the A. B. C. audit. This is but the beginning.

Advertising is being put to a test to-day, which it can meet if you put circulation to the test of A. B. C. reports.



*Canadian Machinery* is a member of The Audit Bureau of Circulations.

# Goulds Triplex Pumps Reduce Pumping Costs

Vast numbers of Goulds Pumps are working perfectly day and night, in thousands of plants, great and small. There is no doubt as to their successful performance. They are the Leaders in reliability and operating efficiency. May be driven by any motive power. They will show a saving of two-thirds and more in pumping costs over direct-acting steam pumps of the same capacities and pressures.

# Poole Turbo-Gear Has an Efficiency of Over 98 per cent.

The Turbo-Gear is a mechanical step-up or step-down speed transforming device. It is coupled between and directly to the prime mover and the driven unit. Turbo-Gear is pure torque transmission. There is no side strain on shafts or bearings. Forced lubrication, economy of space and maintenance, and absolutely quiet running are some of the other factors behind its 98% efficiency—plus.

# Machining A Motor Shaft in Two Operations

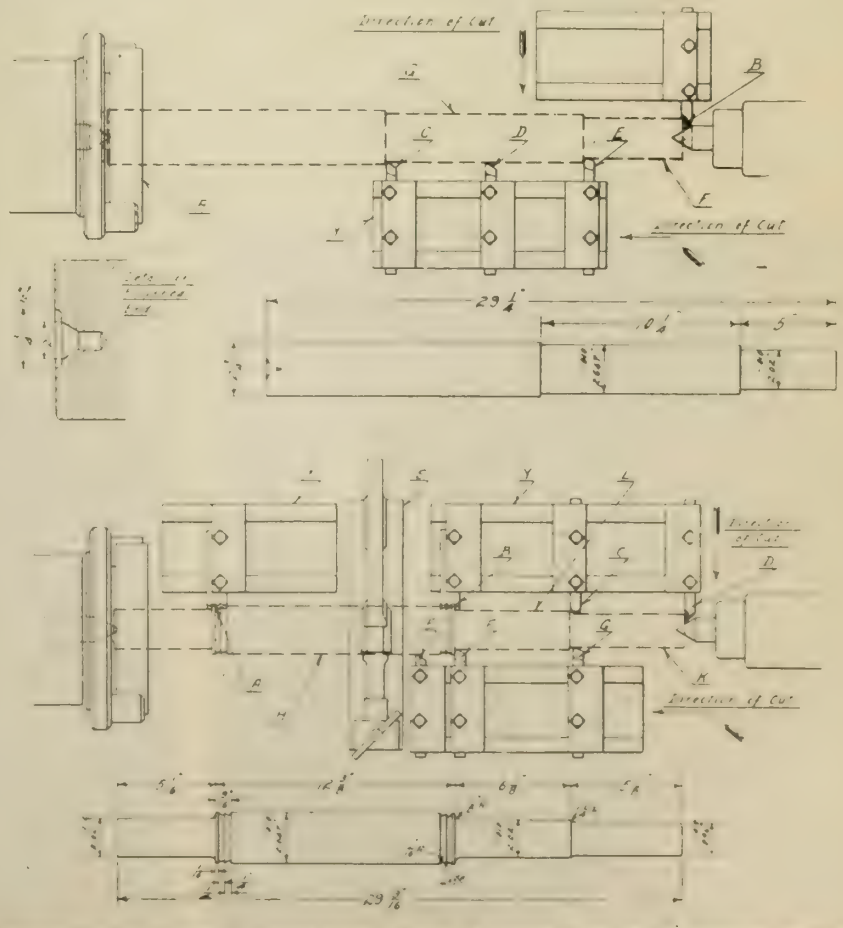
## Two Machines Used, One Operator Running Both—Machining a Three-Step Cone Pulley—Two Operations Necessary—Producing Pistons in Three Operations. Tool Set Ups Shown in Each Case

By H. A. LOUDEN

WHEN machining quantities of duplicate parts it is an understood fact that if a high production rate is desired, one must use a machine suited to the work. In the following artiele examples of work which have been produced on the type of lathe known as the Fay automatic will be shown. On these machines are a sufficient number of tools, so that the turning or facing cuts on the various surfaces can be taken simultaneously. This is made possible by the construction of the lathe, which provides multiple tools for both facing and turning, operated by independent cam movements. In this way the machining of all the surfaces may be accomplished in the time taken to make the longest single cut.

These machines are automatic in all their movements. When the tools reach the end of the cut the drum is thrown into fast motion and the tools are returned to the starting point and the machine stops.

The work which we will first consider is the machining of motor shafts. Two machines are used in this case, one being set up on one end, referred to under first operation, the other being set up on the other end, referred to under second operation. One operator runs both machines and the machines are stiff enough so that the work is finished ready to grind with one cut.



### First Operation

The layout of the tooling equipment is shown in Fig. 1. The outline of the work is shown by dot and dash lines. The shaft is held between centers, and driven by a double end dog "A." The dog is rotated by driving pins on the face-plate of the machine. An equalizing drive is obtained on account of the face plate being allowed to float.

In operation, the arm on which the rear tool holder "X" is mounted swings forward, thus causing the tool holder and the tools to rock towards the work in the direction indicated by the arrow adjacent to this tool holder. When this occurs, tool "B" faces end of shaft and forms radius. At the same time that this tool is being operated, the carriage "Y" is fed in on an angle until the three tools "C", "D" and "E", mounted on the carriage are taking the proper depth of cut, and then longitudinally as shown by the arrow, turning the two diameters "F" and "G." The two tools "D" and "C" divide the turning of the diameter "G" between them, thus cutting the turning time of this diameter in half. It is evident that the shaft is machined in the time necessary to turn one-half of diameter "G" or the part turned by tool "C," or tool "D." Production on this shaft is sixteen to twenty pieces per hour.

### Second Operation

The tooling for the second operation is shown in Figure 2. The shaft is re-

UPPER VIEW, FIG. 1—SHOWING FIRST SETTING ON THE MOTOR SHAFT
LOWER VIEW, FIG. 2—SECOND SETTING ON THE SAME SHAFT

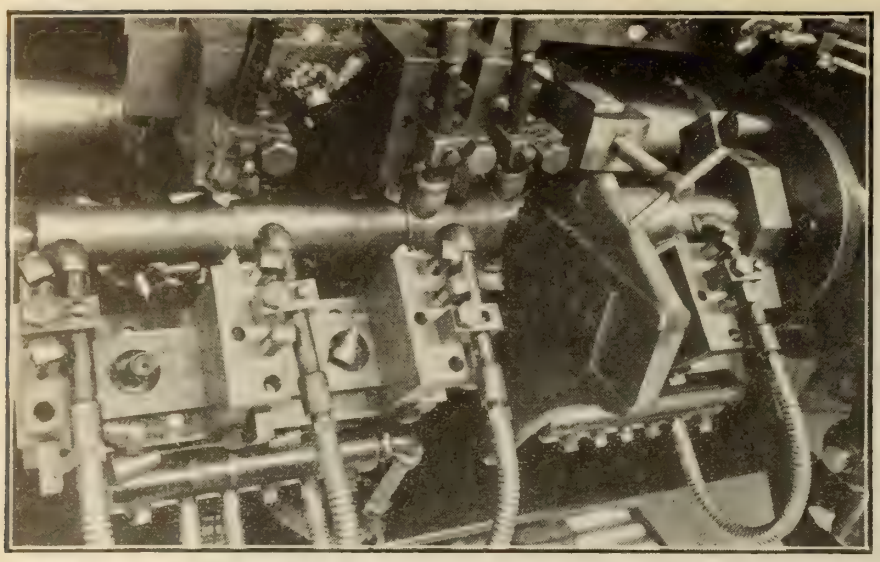


FIG. 3—CLOSE UP OF MACHINE WORKING ON MOTOR SHAFT AT SECOND SETTING.

versed, and held and driven as in the first operation. The shaft is supported by the use of a steady rest "S." In this operation the machine is equipped with two rear tool holders "X" and "Y." These holders are moved forward in the direction shown by the arrows. Tools "A" and "B" face and form oil deflectors. Tool "C" faces shoulder, and tool "D" faces the end and forms radius. At the same time that these tools are cutting the carriage, carrying tools "E", "F" and "G", feed in on an angle to the proper depth of cut, and then longitudinally toward the headstock as shown by arrow turning the three diameters "H," "L" and "K."

Figure 3 shows the machine set up on this operation. The shaft is machined complete in the time necessary to turn diameter "L." It will be noticed that on account of all the shoulders being faced on this one machine, the shoulder lengths on the shaft all come absolutely uniform. The production is 16 to 20 per hour.

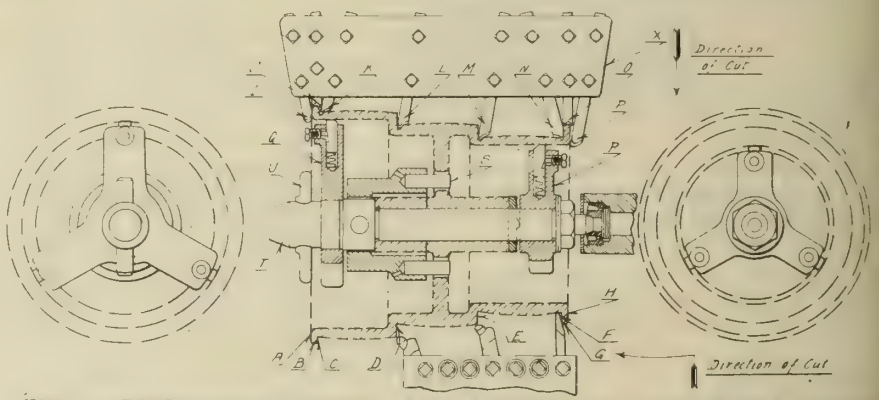

FIG. 4—TOOLS FOR TURNING AND ARBOR FOR SUPPORTING CROWN PULLEY.

**Machining a Three-Step Cone Pulley.**

Two machines are used in the operations on pulleys. One operator runs both machines. The first machine roughs while the second machine finishes. The work is mounted on arbors, and held between centers. Three arbors are provided so that the work is being changed on one while the other two are in the machines. This eliminates having the machine idle while a finished pulley on an arbor is being replaced by a rough one.

**First Operation**

The tooling provided for rough turning and rough facing a three-step cone pulley is illustrated in Figure 4 in which the outline of the work is shown by dot and dash lines. The work is mounted on arbor "T" by means of a reamed hole through the pulley hub, and is located longitudinally on the arbor by the hub faces. The hole and hub faces of the pulley are finished in a preceding operation. The rims of the two outer steps are adequately supported on the inside by the three-armed spiders "Q" and "R." The arms of these spiders are provided with pins that are forced against the work by coil springs placed in the same holes as the pins. When the pins are in con

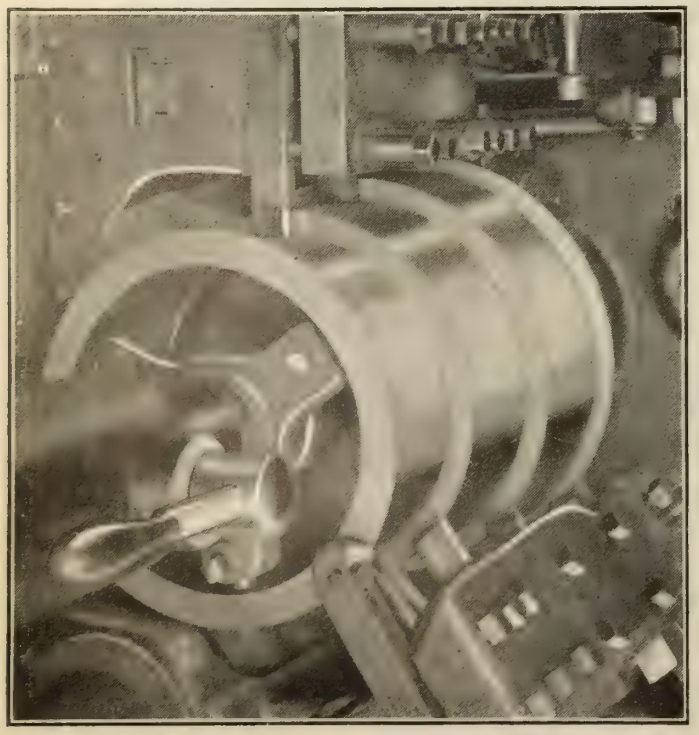

FIG. 5—SECOND OPERATION ON THE PULLEY.

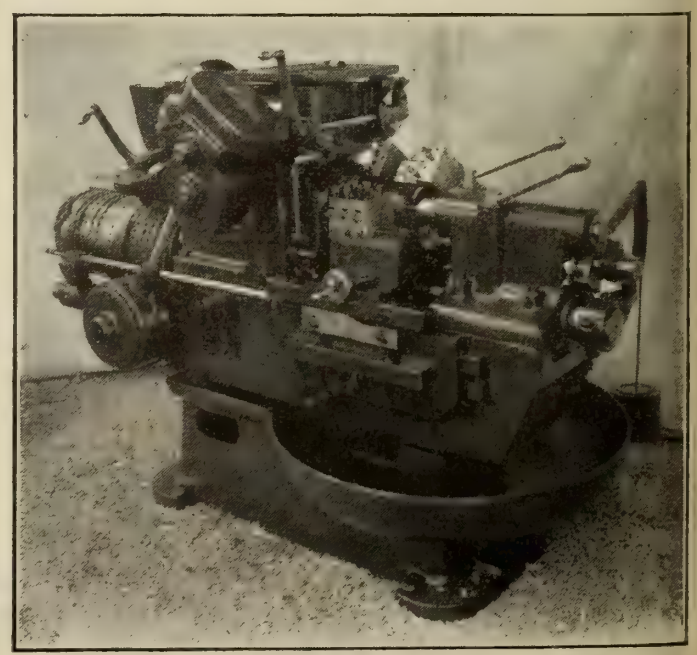

FIG. 6—SHOWING THE TYPE OF MACHINE USED.

tact with the pulley rim they are clamped in position by means of screws. A floating drive is obtained on the arbor through the pin "U," which is flatted off on an angle on both ends and allowed to turn to equalize the driving pressure, the pulley in turn being driven by pins "S" which extend through the holes in a rib on the pulley beneath the middle step. These pins are mounted in an equalizing sleeve as shown.

In operation the arm on which the rear tool holder "X" is mounted, swings forward carrying the tool holder and the tools toward the work in the direction indicated by the arrow shown adjacent to this tool holder. When this occurs, surface "A" is faced by tool "I"; surface "B" is formed by tool "J"; surfaces "C", "D", "E" and "F" are faced by tools "K", "L", "M" and "N"; surface "G" is formed by tool "O" and surface "H" is faced by tool "P." At the same time that these tools are being operated, the carriage "Y" first moves transversely until its tools are taking the proper depth of cut, and then longitudinally, during which movement each of the three steps on the pulley are turned by one of the three tools mounted on the carriage. The direction of the carriage movement is indicated by the arrow in the lower part of the illustration. The pulley is roughed complete in the time necessary for one of the tools on the carriage to turn a single step.

### Second Operation

Figure 5 shows the machine in operation for finish turning and finish facing the various surfaces, during which operation a curved crown is produced on each of the three steps. A former with concave face beneath the front carriage gives the tools the required movement for accomplishing the crowning. The actual production on this work is six pulleys per hour, roughed and finished complete. One man running two machines. This style of lathe may be used to equal advantage in the machining of four and five step pulleys, also plain pulleys.

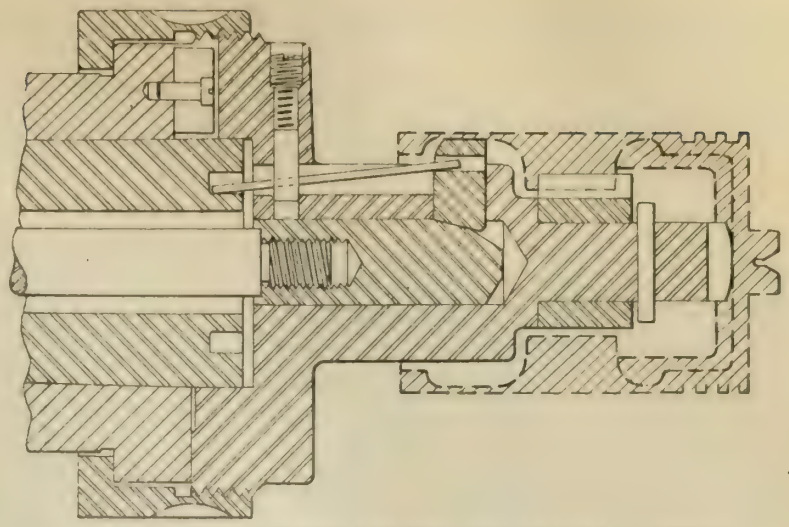

FIG. 7 FIRST SETTING ON THE 3¾" PISTON

### The Machining of Pistons

The method outlined is that proven by experience to be the best one for getting pistons of the highest grade at the lowest cost. The machine used is the short bed Fay automatic, shown at Fig. 6. Before the casting comes to the machine it is placed on a centering mandrel on a sensitive drill press and centered true with the rough core.

The first setting is clearly shown in Fig. 7. The piston is mounted on an air operated fixture provided with three expanding pins "P", which bear against the rough core close to the skirt thereby centering the open end very accurately. The closed end is supported on a revolving ball bearing center, bearing on the center hole above mentioned. This hole having been drilled accurately with respect to the core, the piston is rough turned in this setting true with the inside core so that a piston with a very uniform thickness of wall is produced. The carriage tools rough turn the outside diameter while the back arm tools are facing both ends and rough grooving the piston ring grooves. Enough tools are used in the carriage so that all the rough turning is done during the time required to rough face the closed end.

Production of a piston which is 3 3-4 dia. x 3 3-4 long on this operation, one man, two machines, is 90 to 100 pieces per hour. These figures represent a production that has been maintained over quite a period of time with annealed castings. No. 2 stellite was used for all tools except the grooving tools which were made from high speed steel. The tailstock ram is lever operated, and the machine goes through all of its motions automatically, thus requiring the minimum of attention from the operator.

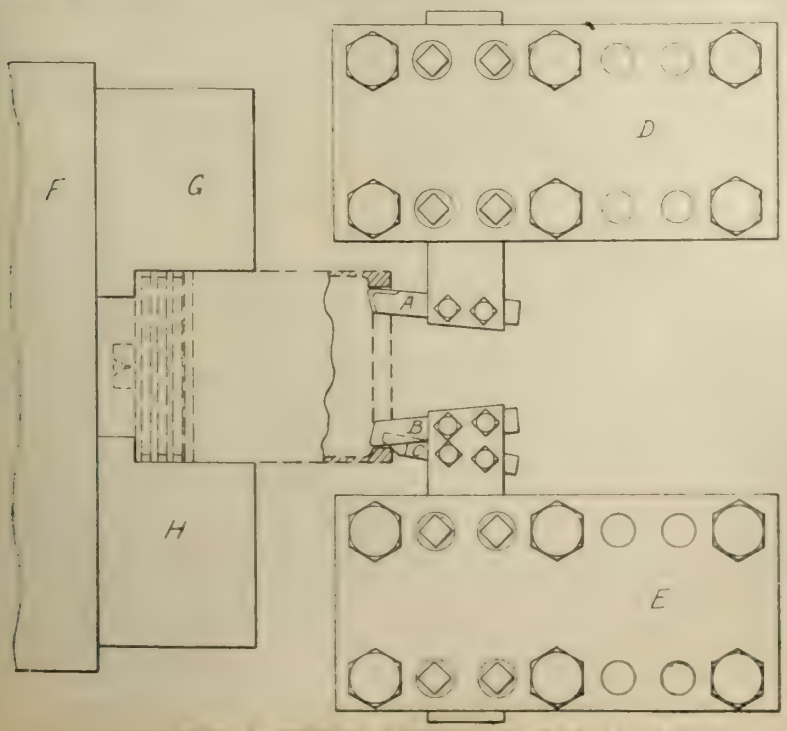

FIG. 8—SECOND SETTING ON THE 3¾" PISTON

### Second Operation

The second setting is shown in Fig. 8. The piston is held in the air operated chuck, and gripped by the outside diameter, which has already been rough turned true with the core. In this operation the skirt is rough bored with a tool mounted in the back arm and finished bored with a tool mounted in the carriage. The resulting diameter being held within .002 so as to be a good fit on a fixture employed for finish turning and finish grinding. The machine holds the pistons within this limit of accuracy without any trouble, and a production has been obtained of 150 to 180 per hour per machine.

In the third setting the tools are mounted as shown in Figs. 9, 10 and 11. Fig. 9 shows the carriage and back arm tools as well as details of the spindle fixture and ball bearing revolving center. Fig. 10 shows details of the auxiliary grooving attachment mounted directly below the back arm tools shown in Fig. 9. The relative position of all these tools is shown by the

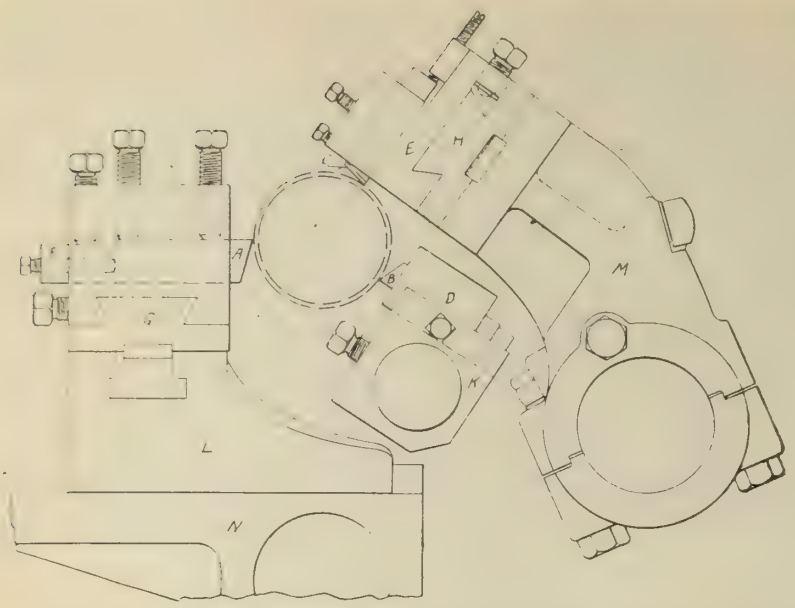

FIG. 11—THIRD SETTING ON 3¾" PISTON, SHOWING END VIEW.

end view Fig. 11. In this operation the outside diameter is finish turned ready to grind during the time that the back arm tool faces down the closed end to a point where the finish grooving tools which are mounted in the back arm begin to cut. During the time that the finish turning tools in the carriage are cutting, the grooving tools mounted in the auxiliary grooving attachment (shown by Fig. 10, and shown below the back arm Fig. 11) take a second roughing cut on the grooves.

The first cut on the grooves has been done in setting No. 1. This cut just described sizes the grooves and lines them up perfectly with the finish grooving tools mounted in this same machine. This cut also brings the grooves very nearly to size, so that the final finish grooving tools mounted in the back arm have very little work to do, and will maintain an accurate width of groove for a long time.

The back arm is fed through its final travel, which is employed for the final finishing of the grooves after all the other tools are through cutting. This method results in finish turning the piston all over in the time required to finish face the closed end of the piston. All the motions of the machine being fully automatic the resulting production is higher than that obtained by any other method. An extremely fine job is also produced. It will be noticed that both ends of the piston are finish faced at the same time that the grooves are finished, and also at the same time that the outside diameter is finish turned so that all the work is perfectly concentric. The only thing necessary to watch in this operation is the locating ring "T" shown in Fig. 9. This ring is renewable, and can be replaced and finished in place on the fixture whenever it gets worn. This ring should be a close fit on the open end of the piston. If the piston fits a trifle tight it is readily pressed into place by the lever operated tailstock spindle. The piston is ejected from the fixture as readily by means of the ejecting pin "U," shown in Fig. 9, which is connected with an air cylinder on the rear of the spindle.

The production on this third setting as described above runs at the rate of 45 to 50 pistons per machine, or 90-100 pistons per operator per hour. Stellite tools are used throughout, except that the grooving tools are high speed steel.

## A TALK ON LAMPS

In view of the variety of purposes for which lamps are used on board ship, states Mr. W. J. Jones in a paper read before the Illuminating Engineering Society, it is not surprising to find a multiplicity of different types in use. At the inception of electric lighting carbon lamps were exclusively used and even now find favor on some cargo vessels. The introduction of metal filament lamps, however, has effected a considerable saving of electrical energy. Although in modern vessels the engines are carefully balanced and the structure designed so as to transmit vibration as little as possible, yet the lamps still experience a considerable amount of vibration of high frequency. In recent years lamps have been specially designed to withstand great mechanical shock, and such lamps are in daily use on the London trams and on railway systems.

## INCREASE IN PRODUCTION

The production of magnesite in the United States in 1920 increased 94 per cent. in quantity over that of 1919. The entire output was made by two States, California and Washington. California mined 63 per cent. more magnesite in 1920 than in 1919 and more than eight times as much as it mined seven years ago. Washington increased its production 109 per cent. over that of the preceding year, making by far the largest output it has yet made. According to the United States Geological Survey, Department of Interior, the total production of magnesite in the United States in 1920 was 303,767 short tons, which was valued at approximately $2,748,150.

# Making Machinists Out of Returned Soldiers

## The Course Takes Thirty Three and One Third Weeks. In That Time The Student Receives Tuition in Shop Mathematics—Shop Practice and Mechanical Drawing. Experience Comes as Matter of Course

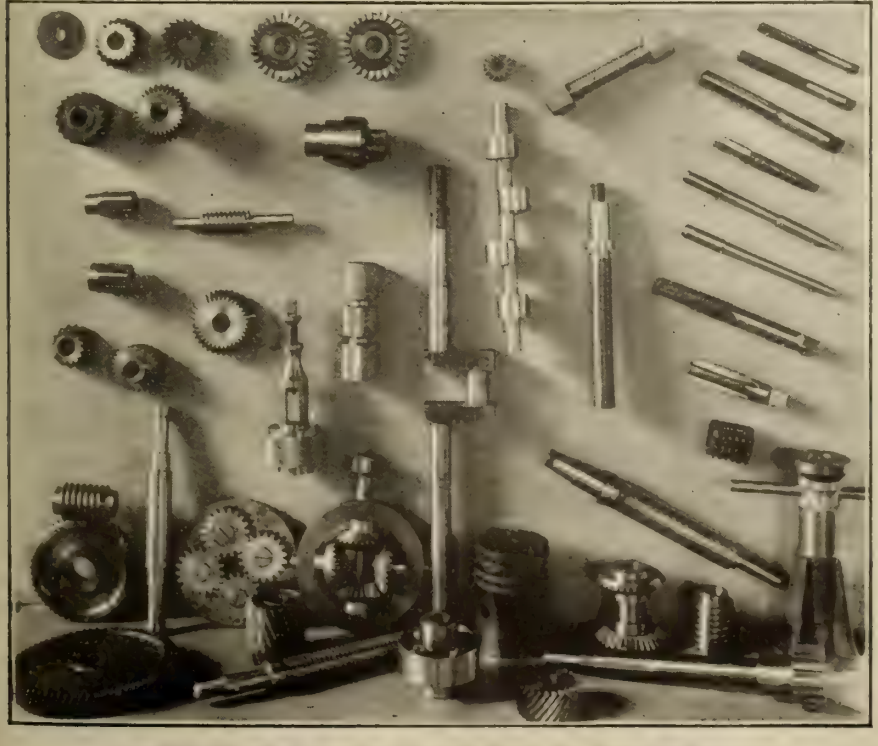
By J. A. McGILVRAY

THE RETRAINING of returned soldiers in the art of machine shop practice, is something which has received close attention at the Nova Scotia Technical College, in their mechanical department. Early in 1917 this work was started, and up to May, 1921, 150 men were trained in machine tool operation, and other branches of the machinist trade. Many of these men are at present successfully carrying on as machinists, and in view of the fact that normally it takes four years to train an apprentice in the machinist's art, it reflects a great deal of credit on those in charge of the school, for the men taking this course only put in a period of eight months.

The shop instruction was first started under the leadership of Prof. Donkin, with Mr. S. Leedman as his assistant, but later on Mr. Leedman relieved Prof. Donkin, who took over the chair of mechanical engineering. Practical machinists were secured as assistant instructors, these men being specialists in their work, and from then on it was up to those learning the trade to gather in as much information as possible in the time at their disposal. No standard time at any work was stipulated, and every man was advanced as he showed merit. Machine tool equipment was added from time to time, until at present they are equipped with the very best in the machine tool line.

The duration of the course, as already stated, is 8 months, or 33 1-3 weeks. Machine shop practice occupies 33 hours per week, or 1100 hours during the course, while practical shop mathematics has 100 hours allotted to it during the course. Drafting occupies 266 2-3 hours of the student's time, the total being 1466 2-3 hours for all three sections. The different studies are taught at various hours throughout the day, this avoiding any tendency to tire of any one particular section.

MAIN BUILDING OF NOVA SCOTIA TECHNICAL COLLEGE, HALIFAX, N.S.



The course of instruction has been carried on without changes since the class first commenced. The above schedule has worked out well, as statistics show that a man with average intelligence and no experience along this line of work can become (if he applies himself) a fairly proficient machine tool operator in 8 months. Of course he lacks experience, but that comes later.

When a man first enters the shop he is carefully sized up by the instructors; his name is entered on the roll, and the time limit noted. He is passed over to the assistant instructor who places him at work on the bench, where he learns how to use his hands, and how to apply them to the use of hand tools such as hammers, chisels, files, scrapers, etc., on a particular job which must be finished by hand tools. On the completion of this job he is allowed to change to other machines, and he is carefully instructed to give him a good start, so that he will apply only methods which are correct.

The time period for the bench may range from two weeks to one month, depending on the ability of the student, and every student starts at the bench on standard, well thought out work. When the term at the bench is finished he is shown the different methods of drilling holes in various metals, both at high and low speed, also the use and abuse of hand taps and reamers, remaining at this work until a satisfactory standard has been reached.

From this he is moved to the shaper where the different methods of shaping metal to form is carefully taught him by the instructor. The various methods of setting up work; the way in which to grind the tools used to do the different operations; a detailed description of the various parts of the machine itself; correct and incorrect ways of operating are all pointed out to him, and, after a few weeks when he presents to the instructor a complete job, and when the application of micrometer or calipers to his work has shown it well done, he is moved to the lathe, which seems to be the desire of all students.

The course of lathe instruction is mapped out carefully, both to help the student, and to save the machine. One of the first jobs usually given to the beginner is to turn a plain spindle 1½ in. diam. by 18 in. long. He is then instructed to select a piece of round steel from the stock rack allowing enough oversize on the rough stock to finish to a given diameter. He is next shown how to cut off the required length in the power hack saw, and the required allowance to leave on for squaring ends. Next comes the use of the Hermaphrodite caliper, and center head square, to enable him to find an approximate center

SOME OF THE WORK COMPLETED BY THE STUDENTS.

before drilling centers in the ends of parts that have to be mounted between lathe centers. The method of fastening the dog to the work is shown, and before placing work between centers he is shown how to start and stop his lathe, also how to engage and disengage lateral and cross feeds.

He is now shown how to grind the tools for this particular operation. He then takes a roughing cut across work to within 3 or 4 inches of head center, changing end for end and finishing the remainder of cut. He is taught to use the calipers as the next cut is to be finished size, and is shown how to grind tools to give a clean, smooth cut. In beginning, the student is usually started below speed until such time as he improves in skill and confidence, then the matter of speed and feeds are taken up and he is shown how to move along at a business-like pace. He is also instructed how to turn tapers both by setting over the tail stock, and by the use of the taper attachments. He is shown how to cut threads on the lathe, both vee and square, right and left hand, single and multiple. There is also a variety of work on the lathe that is required to be done in the chuck or face plate. This work is gone into carefully, and he is taught to use judgment and caution as each job has its own peculiarities, no fixed rule being existent for this class of work. At the end of the time allotted for the lathe the student is transferred to the milling machine which runs hand in hand with precision grinding and other work. The finest work is taught him, this including the milling of slabs, keyways, slots; the milling of gears, worms, spirals; the making of reamers, taps, hobs, and other fluting operations; bevel gears, skew gears, also the making of milling cutters. A brief insight into the tempering and grinding of these tools is given, until at last the student goes out to earn his daily bread by means of the machine tool knowledge given him.

### Mathematics

When a student enters the mathematical class he is first questioned as to his previous schooling in order to ascertain just where he should begin. If he has a good knowledge of fractions and decimals he is put in the advanced class, otherwise he is placed in the junior class. The preliminary mathematics consists of fractions, compound fractions, decimals, percentages, use of percentages, efficiencies and discounts. After the student has shown that he has a fair knowledge of the preliminary work (I say fair owing to the short time that he is in the class) he is transferred to the advanced class, this dealing with practical shop mathematics.

The subjects taught are the use of formulae, circumferential speeds, grindstone and emery wheels, cutting and belt speeds, ratio and proportion, direct and inverse proportion, speeds and diameters of pulleys, gear ratios, compound gear and pulley trains, area of circles, square root, triangles and rectangles, levers and wheels, axles and incline planes. The student studies also each machine in the shop separately. For example, on the milling machine he receives instruction on the index head; compound and differential indexing; the spiral head; cutting spur gears, bevel gears and worm gears; also how to figure the proportions of such gears.

On the lathe he is taught how to figure his gears to cut any thread. Tapers and speeds are also considered. Each

FREDERICK H. SEXTON, D.Sc., L.L.D., PRINCIPAL NOVA SCOTIA TECHNICAL COLLEGE.

machine is taken in this manner and the student is encouraged to apply his theory to his work in the shop. Examinations are held at intervals to find out how students are progressing, and special instructions are given to the slower students. If a student wishes to enter this course, but his education is not sufficient, he is sent to the re-educational class. This has proved of great benefit, as students show a decided improvement on returning.

### Machine Shop Drafting

This part of the course is complete within itself, giving to the student a clear and concise training in the art of making a working drawing both from sketches and from actual objects or parts, thus enabling him to use blue prints, from which he can make a machine any part in the course. He receives good practice in the reading of prints as all his instructions are given him, when he is sufficiently far advanced, by sketches or by blue prints. The photograph at Fig. 1, showing work completed, tells a story in itself, and great credit is due Frederick H. Sexton, D.Sc., L.L.D. the principal of this technical college, for the success of the course. One must see the men at work to fully appreciate the careful instruction afforded them.

---

## THE ORIGIN OF NATURAL OIL.

In a paper which he recently read before the Melbourne Section of the Junior Institution of Engineers, Rear-Admiral Sir William Clarkson advanced the theory that natural oil is of vegetable origin. Life must, Sir William thought, have originated on the earth in a vegetable form, for it is impossible to conceive animal life without food of some kind, and all our experience tends to show that this food must, in the first instance, have been of a vegetable nature. The original vegetable life must also have grown in water and not on land, for in those early periods—the crust of the earth being thin and excessive rainfall and tremendous erosion being the prevailing conditions—the surface of the land would not have, at first, been in a sufficiently stable or fit condition to support terrestrial growths. It is natural to suppose that the heat, and the saturation of the water with carbon-dioxide, would supply all the conditions necessary for very luxuriant aquatic growths. Terrestrial growth must necessarily possess qualities which need not be present in plants growing in water. For instance, in order to support themselves in air, they must possess strength and fibre of an altogether different nature to that required by aquatic plants, which are supported by the water in which they grow. It is not straining things very seriously if we suppose that for this reason terrestrial plants, in process of time and under favorable conditions, have been mostly converted into coal and other carbonaceous deposits; aquatic plants being, from their composition, incapable of forming coal, have by a different process of deposition and decomposition, been turned into oil. We do not find any evidence of the presence of coal in the older geological periods, when aquatic growth would be possible. On the other hand, as before mentioned, we do find oil in rocks belonging to those periods. This affords fair presumptive evidence that natural oil—provided always that it is of organic origin—has been produced from the decomposition of organic material of aquatic origin.

Some years ago the Naval Board investigated the occurrence of an alleged oil deposit found in quantity over a large area in the south-east of South Australia. This substance, which has been named "coorongit," is a tough substance resembling india-rubber. It occurs in layers of from ⅛ in. to 1 in. in thickness under the sand. Mr. Marcus Bell, the Commonwealth Superintendent of Laboratories, reported that it "burned with an oily smell, and that, by means of a solvent, 25 per cent. of oily matter was extracted which was of vegetable origin." There appears to be no definite evidence that it has been originally forced up from any considerable depth to the surface as a liquid, and it has most probably been formed where it is found, resulting from the decomposition of masses of seaweed thrown up on old ocean beaches. This is in a measure confirmed by the presence of small wiry twigs in the body of the coorongite identical, to all appearances, with similar twigs found on the sea beaches intermingled with the seaweed.

Sir William suggested that instead of spending money and time in an endeavor to produce power alcohol from molasses and foodstuffs, by means of fermentation and distillation, with very doubtful chances of commercial success, it might be advisable to try what can be done with seaweed. Find a suitable ferment, he said, put it to work under suitable conditions, and observe the result. Foodstuffs are required for food; no one wants seaweed, and it is available in unlimited quantities. He dd not suggest that hydrocarbon oil could be produced commercially in quantity by any such method—the element of time necessary to complete the conversion would most probably negative any commercial success—but such an investigation, if successful, would, at any rate, go far to settle the very vexed question of the origin of natural oil, and would give an immense impetus to prospecting.

The latter part of the paper was devoted to a consideration of the possibilities of finding oil in Australia, and to descriptions of the wells which have been sunk already.

# Keeping Tab on the Operations and Tools Used

## How do You Determine an Operators Value?—A System That Keeps Track of Every Special Tool, Jig, Reamer, Drill, etc. Operator Must Give Definite Reason for Spoiled Material

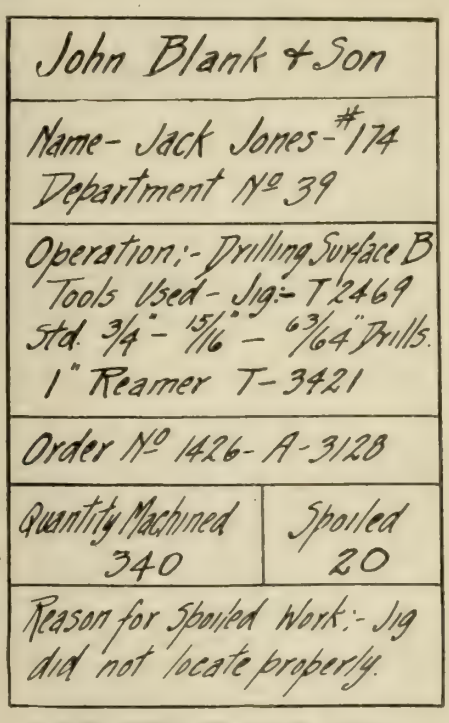
By ROBERT MAWSON

HOW do you determine whether a workman is worth more money or not, in the event of his requesting an increase? Do you call in your foreman and depend solely on his advice or have you some definite data on each worker that determines his worth to you?

A system that has found favor by one concern is shown in the illustration, and it has solved very satisfactorily for them the problem of increases.

Every special tool such as a jig, fixture, reamer, drill, etc., is marked, in this plant, with a number, and it is kept in the tool room. The detail drawings of the different elements are marked on the various surfaces operated upon, with letters such as A for surfaces, B for bosses, etc.

Referring to the illustration, it will be seen how this works out. The spaces on card are to be filled out by the foreman or his assistant, giving the machine operator's name, department, order number of the job and drawing number, this last information being also the number of the detail to be worked upon.



Another line gives the number of each tool required when machining the particular operation in question. In the example given the operation calls for drilling surface B and requires jig T-2469, standard ¾ inch, 15-16 inch and 63-64 inch drills and 1 inch special reamer T-3421. The order number of the job is 1426 and the part drawing A-3128. The quantity to be machined is 340 of part A-3128.

After the drilling machine operator has received the filled out card as described, he takes it to the tool room storage and receives the various tools noted in a box, the same being checked out against his workman's number, which is shown to be 174. In the meantime a tote box has been placed at the drill press by one of the helpers containing 340 unfinished castings of this part A-3128, also the working drawing of the same.

After the first piece has been machined with the operation noted it is inspected and if found correct, the workman is told to complete the work. If any mistakes are found the cause is investigated and remedied. After the 340 parts have been finished by the machine operator they are inspected and should any be found spoiled, the card is marked accordingly. Supposing it be found that 20 are defective, the card is returned to the machinist and he has then the opportunity of noting on the card why he spoiled these pieces during the machining operation.

Let us see what reasons are sometimes given. One would be, "Jig did not work right." Under these conditions, it will be the foreman's duty to find out if the jig does not function properly and at once take steps to correct it. The excuse would then be considered valid and the card marked "Reason sufficient."

Again the reason might be, "Castings bad," and this would cause the work being spoiled and the card marked in a similar manner to that already noted. However, it might be found that though the reason given was "Jig not right," after investigation it could be proved to the man that he was at fault in not using

THE TYPE OF CARD USED.

the jig properly after being properly instructed and then the card would be marked "Reason insufficient." The cards are then turned over to an assistant in the superintendent's office, who makes a rating card for each man monthly, computed on the percentage of spoiled work actually counted against him. It might be noted here that where the cards are being of course deducted.

With this simple method of keeping track of a man's work, the superintendent was provided with certain knowledge of all the various men's ability. When any man was showing a high percentage of efficiency, in other words when his spoiled work was low it was considered good policy to increase such man's wages, as by so doing the man realizes that his work is being appreciated. On the other hand supposing a man came to ask for an increase saying that he thought he was worth one, by referring to his efficiency cards for the past, say, three months which had been compiled from his actual work we could at once see whether he was improving in his work or not and act on the wage question accordingly.

### HOW ABOUT DUST?

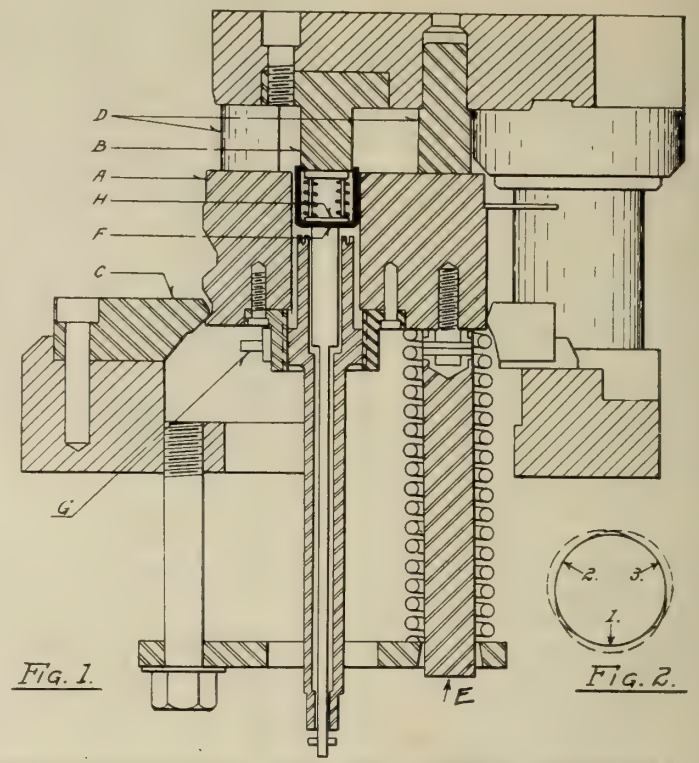
Is your plant free from dust? Of course it's not. It may be very clean, but there is always a certain amount of dust existent. The chief question is, "How dusty is the air?" Knowledge as to the degree and composition of such dust is important, for certain amounts and sorts of air dust seriously affect the lungs and predispose those who breathe them to tuberculosis and other diseases.

Dr. O. M. Spencer, of the U. S. Public Health Service, speaks of this matter in a recent report of the Service. He shows that neither the fact that the exhaust pipes, etc., required by law appear to be properly functioning nor the use of wet instead of dry processes in grinding, polishing, and the like make it at all certain that the dustiness in a given plant is what it should theoretically be. He finds that many exhaust pipes do not in fact exhaust as they are supposed to do; and that under certain conditions some wet processes create much more dust than dry ones. Only actual "dust counts" show the real dustiness of the air that the workmen must breathe; and such counts should be made periodically to check the theoretical conditions.

To determine how unhealthful the dustiness of any particular plant process may be the composition of its dust should be ascertained and its effects interpreted by standard tables, which Dr. Spencer urges should be worked out for the various industries. Different industrial processes produce dusts which differ greatly in injurious properties.

### WIRELESS DEVELOPMENTS IN CHINA

"Finance and Commerce" states that the Mitsui Bussan Kaisha are constructing a high-power wireless station about nine miles east of Peking. The sending station in the east, and the receiving station in the west are about a mile apart. The power-house and four of the six steel towers, each 700 ft. high, are finished; the remaining two towers will be ready within two months. The construction of this plant, which was commenced last April, was delayed by prolonged negotiations with over 300 small landowners, who had to be bought out. The contract with the Chinese Government was signed on February 21st, 1918, but no time was set for the completion of its provisions. The Government is reported to be considering the establishment of wireless stations at Chefoo and Weihsein, in Shantung, thus covering the district east of the Kiaochow-Tsinan railway.



# Construction And Action of New Trimming Die

## A Patented Tool That Trims the Surplus Metal—Special Action Causes the Cutting—In Place of Downward Movement of Punch a Lateral Oscillating Movement Accomplishes the Operation

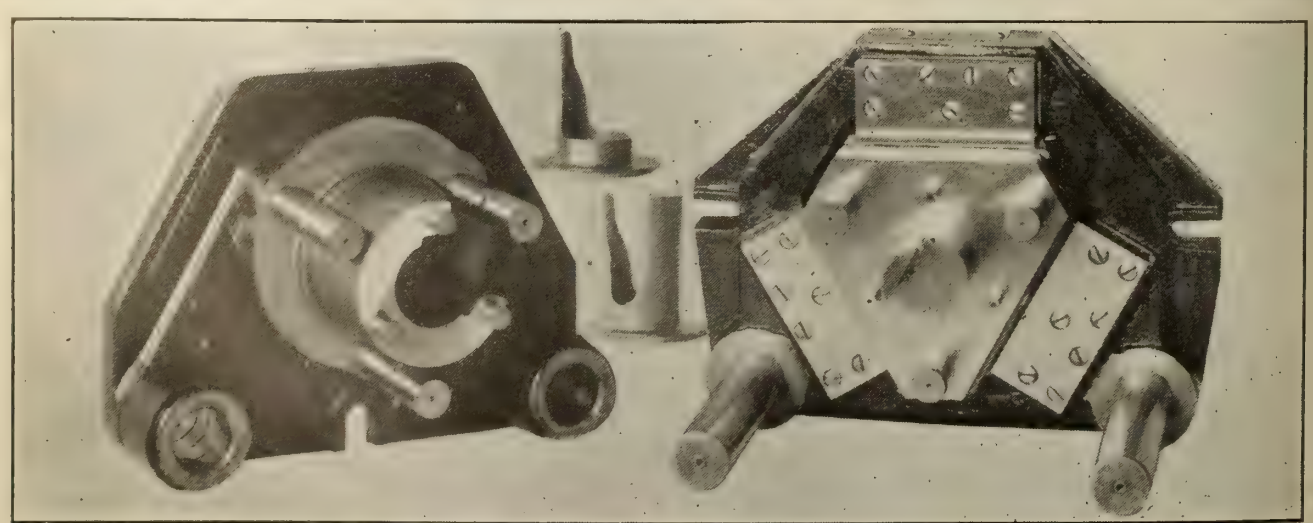
A new patented tool that is being introduced by Jos. P. Cleal, of Toronto, will be of interest to manufacturers who use parts drawn into various shell shapes by the punch press. This tool, known as the Brehm trimming die, trims the surplus metal from the shell, leaving the part with a perfectly straight edge. These dies can be built to trim round, square or irregular shaped shells.

One of the principal points of difference between these trimming dies and the ordinary blanking dies is the action that causes the cutting. In a blanking die the cutting is caused by a downward movement of the punch; in the Brehm trimming die it is caused by a lateral oscillating movement of the die block.

In the construction of the die, the die block "A" in Fig. 1 is triangular in shape, having cams cut on its sides similar to the one shown except that they are so placed as to operate in rotation. The shell to be trimmed is placed in the die as "F," and as the press slide descends the punch "B" enters the blank. Three studs mounted on the punch holder—two shown as "D"—which are slightly longer than the punch "B," come in contact with the die block and force it down on springs. As seen in the cut, this downward movement of the die block will cause the cams on this piece, and the cam on the permanent female cam "C," to operate, forcing the die in a lateral direction, which in connection with the punch causes the cutting operation. After the first cam has operated, the cam on the second face operates in a similar manner, and then, in rotation, the third set of cams. Take two coins of the same diameter and place them together but off centre. By watching the edges as they meet when the coins are moved, an exact duplicate of the shear movement of the die will be given. In Fig. 2 the direction of the different movements and the amount of scrap stock removed by each cam is shown.

SECTIONAL VIEW OF THE DIE, SHOWING PRINCIPLES INVOLVED.

One feature of this trimming die is its simple construction. The die block "A" with the three attached studs, one shown at "E," are the only movable parts. These studs are merely for holding the springs in their proper places and to prevent them from buckling during the operation of the die. To sharpen the die one of the female or permanent cams "C" is removed, allowing the die block to be lifted out. After removing the studs "E" and the threaded bushing which carries lock screw "G," the die can be ground on an ordinary surface grinder. Throughout the life of the die the grinding does not affect the timing of the cams. As the top surface of the die block is ground away, the screw support which determines the length of the trimmed shell can be lowered. Lock screw "G" holds this part permanent during the operating of the die. The punch is ground in the same manner as



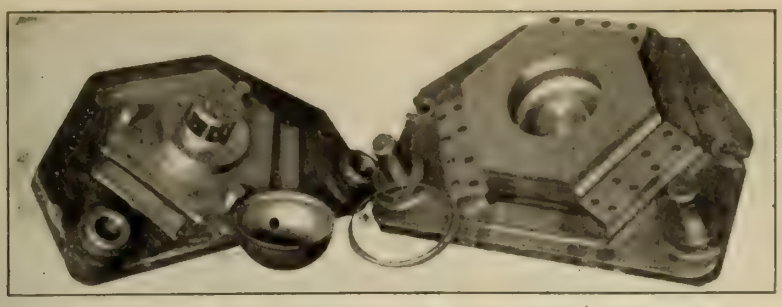


FIG. 3—A TRIMMING DIE FOR MAKING THE PIECE SHOWN.

ANOTHER DIE DESIGNED ON THE SAME PRINCIPLE

a blanking punch and a slight amount shorter than the pressure studs mentioned as "D" — this variation making the clearance between the punch and die when in operation. The grinding of either punch or die does not change their shapes so as to affect the shells to be trimmed. The spring pad "H," fastened to the punch, is for holding the blank stationary during the trimming operation.

Owing to the shear movement of the die they are said to have an unusually long productive life. The minimum amount of grinding space allowed is one-half inch. Dies built for shells of one inch or under have oil-hardened die blocks with carbonized female cams. All larger sizes have die blocks of carbonized steel with tool steel inserted bushings which do the cutting. All cam faces on both the female cams and the die blocks are ground to their proper dimensions. Carburetor bowls, trimmed in this type of die are said to have shown a greater degree of perfection than those trimmed in a lathe, as the bowl is not distorted by clamps in any way during the cutting operation. Shell drawn from extremely thin metal, such as copper, aluminum or fibre, are as easily trimmed as those of more substantial build. Parts made from .010-inch to ⅝-inch stock from ¼ inch to 21 inches in diameter and from ⅛ inch to 10 inches deep have been successfully trimmed.

When operating the die, the pieces to be trimmed are merely dropped in the opening in the die block. There are no stop pins, clamps or nests or other attachments to retard the speed of the operation. If the press is inclinable and equipped with compressed air, which can be used to eject the shells, a very high speed of production can be obtained. In a number of cases one die has been built to trim several shells of different diameters and lengths. This practice is limited in small dies to minor variations. In the trimming of automobile brake drums, fifteen different sizes are being trimmed in one die, which takes care of the following variations: from ⅜-inch to ¼-inch stock, from 21 inches to 15 inches in diameter and from 9½ inches to 6 inches in depth.

In Fig. 3 a die for trimming a piece not entirely straight is shown. The projection on the edge of the shell is formed on an ordinary horn die while the straight part is trimmed by the trimming die. A similar combination of dies can be used to advantage in trimming metal boxes when the hinges are formed on the edge as part of the box or lid.

## MACHINING LOCOMOTIVE BOILER STAYS

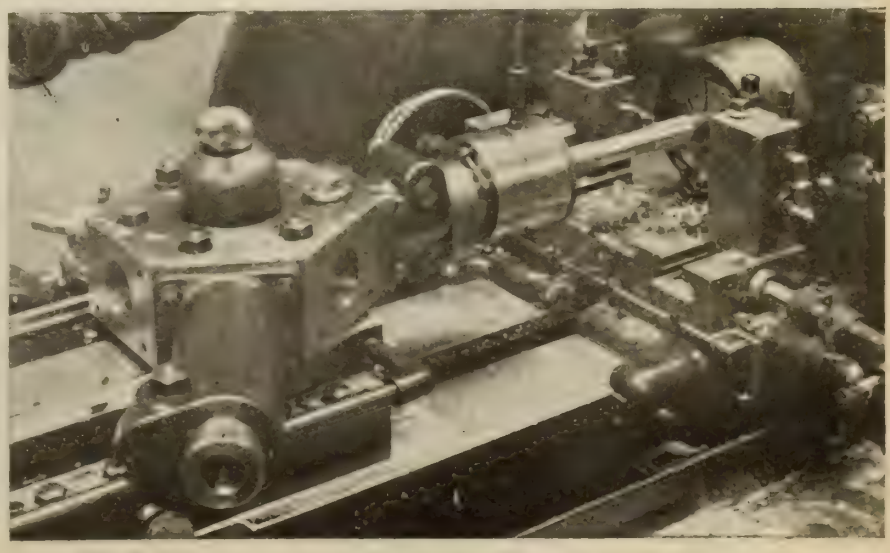
J. H. Moore

LOCOMOTIVES, like human beings, do not always remain in the pink of condition. Constant service of a locomotive causes wear, which in turn necessitates repair. One of the parts that frequently requires repair is the firebox. New stay bolts are often necessary and generally the old holes for the bolts are retapped, and larger stays inserted. This process is continued until the maximum allowable size of stay bolt is reached.

When large quantities of such bolts of similar size are required, an automatic machine is generally used, but for regular repair work where the bolts vary in size and do not come through in quantity, an automatic is not essential, and in fact is a considerable expense. The Alfred Herbert, Ltd., Coventry, England, have had considerable experience on this class of work and their Toronto office, 1-3 Jarvis St., has furnished us with some interesting data showing how, with the aid of a simple attachment, they use their regular No. 4 capstan lathe for such a purpose.

Referring to Fig. 1 we see the attachment as used for machining copper and steel stays. The copper bar, which is drawn about .010 inch over nominal size, is gripped in the draw-in chuck of the lathe. On the first capstan face is an adjustable stop against which feeds the bar, thus regulating the length of the feed.

On the second turret position there is a holder fitted with a cast iron sleeve bored an easy fit on the bar, this supporting the end of the stay. A tool at the back of the cross slide is meanwhile fed into the depth of the clearance portion. On engaging the automatic feed to the turret slide, a boss on the sleeve-holder pushes the slide along, the traverse of course cutting the clearance portion.



Threading is the next operation, and this is accomplished with a Coventry self-opening die head. Owing to the gap of unthreaded portion between the two ends, it is necessary to provide some means of maintaining the two threaded ends in continuous pitch. This is accomplished by coupling the die-head up to the chasing saddle. A notched, hardened steel collar is placed at the rear of the die-head and a block carrying a plunger designed to engage with this notch is carried on the front of the cross slide. The die-head is brought up into position at the end of the stay, and the cross slide moves along until the plunger is a little to the right of the notch.

On engaging the chasing mechanism, the cross slide moves inward, thus compressing the plunger. The chasing saddle now commences to move and when the plunger is opposite the notch it snaps in and carries the die-head and turret slide along at the correct pitch.

As soon as the die-head reaches the end of the first thread, the friction clutch in the headstock is thrown over by hand to the fast speed in order that the unthreaded gap may be speedily traversed. As soon as the die-head reaches its proper position for the second thread, the speed is reduced and the second portion of bolt is threaded.

The chasing saddle is automatically brought to rest at the end of the second threading, this preventing any danger of overrunning. The die-head now pulls off and opens. On disengaging the chasing mechanism, the saddle moves outward

(Continued on Page 44)

VIEW SHOWS THE DIE HEAD IN POSITION FOR THREADING.

# WELDING AND CUTTING

## Are Studs Used In Arc Welding Merely As Pegs?

### Steel Studs Should be Properly Distributed—It Does Not Harm Steel to Strain It, Even beyond Its Elastic Limit—Various Examples of Work Welded Are Shown

By C. J. HOLSTAG

THE writer encounters the prevailing notion about the country that in the electric arc welding of cast iron, studding is resorted to to entangle the parent metal in the metal of the weld, similar to the wooden skewer stuck in a piece of meat prepared for roasting. Such is absolutely not the case. This method of studding was thought out, designed and developed; and my engineering spirit resents the inference that the studs are placed there to function similarly to the pegs in a shoe.

Assuming that steel can be welded to cast iron where the parts are free to align themselves, which assumption is a fact, the use of studding comes in where the weld is in such a position that the parts are not free to align themselves to the contracting strains which result during cooling. In the latter case, a steel weld made to cast iron without studs looks fine until just about the time it is being most admired during cooling, when it invariably cracks along the edge of the weld. This is easily explained when we consider that steel has approximately four times the strength of cast iron. The definite location of the break comes about because the cast iron next to the weld has become chilled cast iron, no matter whether it was originally so or not, and a sharp demarcation of structure together with a possible layer of weaker cast iron causes the break invariably to take place in this layer of cementite.

If, however, steel studs are properly distributed along the face of the cast iron to be welded or adjacent to the joint, so that the weld cannot pull away from the cast iron, the cooling strains result in stretching the steel weld, and the union between the weld and the cast iron and steel studs is maintained as it was made.

That it does not harm steel to strain it even beyond the elastic limit, is a fact not generally known; and I would refer any doubter of this to tests where the ultimate strength of steel has been increased by stretching it beyond the elastic limit. To make this clear, it is only necessary to refer to the well known fact that working steel increases its strength and other desirable physical properties. The point I am trying to make is that it does not injure the weld to subject it to strains even beyond the elastic limit. Of course it may happen that these strains are such that, in work done too rapidly, the weld stretches beyond the ultimate strength and a crack appears. This occurrence is no cause for apprehension, because this crack can be veed out and rewelded, in which case you ar welding steel to steel, and the crack be ing much smaller than the original one the break is not likey to occur again.

How to insure the proportioning o the studs so that the weld does not pul away from the cast iron is a very simpl engineering problem, now that the wa has been shown; but one that require real initiative on the part of the pioneer As nearly as I can find out, the man t whom the world is indebted for thi method of successfully welding cast iro is Mr. Joseph McAllister of the Ne York Central Railroad. It was he, wh upon discovering the ordinary troubl in welding cast iron, developed this stud ding system, not by guess work, but b design, having had similar problems t contend with in boiler construction. was he, who, together with Mr. H. A Currie of the New York Central Rai road and Mr. D. H. Wilson of the Eri convinced the Navy Department tha the interned German ships' damage cast iron parts could be successfull welded. Mr. McAllister laid out th first successful job on these ships an his welders, trained in this work, mad possible the speedy restoration of thes engine parts.

Remembering that steel has fou times the strength of cast iron, the prol

A FLYWHEEL WELD, A LARGE CASTING WELDED SUCCESSFULLY, AND A PORTION OF AN ENGINE FRAME PATCHED. NOTE—THE LATTER HAS BEEN TURNED UPSIDE DOWN THROUGH AN ERROR.

ken is to so proportion the studs that the ratio of the cross section of the steel to the cross section of the remaining cast iron is something less than four to one at any one section that will be subjected to cooling strains at one time. This, in general, is a very simple and easily applied method and means in general, large studs for large sections and smaller studs for smaller sections. Common sense together with welding experience is required in placing the studs. The writer has seen this studding method abused horribly by people who evidently did not understand why they were using this method; and there is no doubt that some of the unsuccessful work done by amateurs is partly due to the prevailing opinion that the studs are simply there to function as tent stakes. That this is not true, can also be seen from the fact that the steam tight joints on cast iron can be made by this method, showing that the weld to the cast iron has been maintained in full efficiency by the use of the studs.

Another very useful application of studding is the use of large studs as an anchor or nucleus for breaks in casting such as gear teeth. One to three of these large anchor studs, together with some smaller regular studs appropriately distributed will provide the necessary weld strength to the cast iron as well as strength to withstand some shear and thrust strains. The weld, built up to size and machined off, furnishes a perfect wearing or bearing surface. This latter method of studding is also applicable to cast steel, where the original section has not been adequate to withstand the strain.

Details of how to accomplish this studding which are not explained by the photographs are:

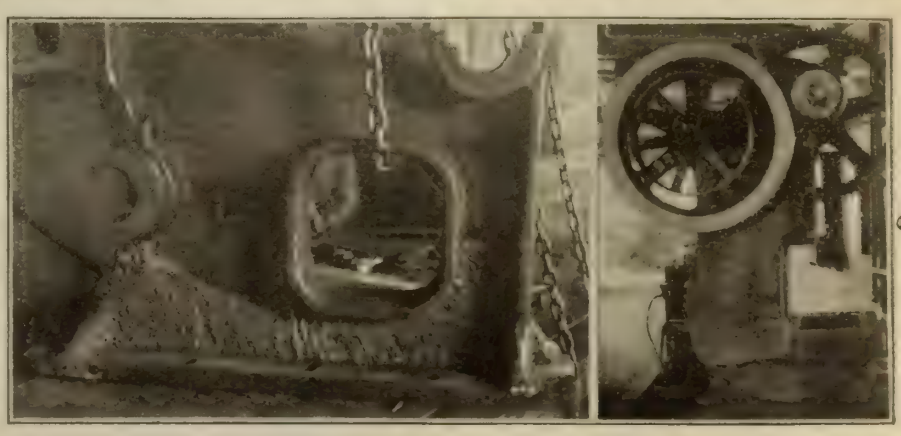
First: Vee out the crack on both sides of the break from one surface; if only one is accessible, or half way from both surfaces if both are accessible for welding; saving enough parts of the original break to keep the piece securely clamped in alignment. Before any of the welding is done, the stud holes are to be drilled and tapped with a bottoming top, and the studs screwed in tight, completely filling the hole for a distance of at least four times the diameter of the stud. A convenient way of doing this is to have rods threaded for their entire length, screw these in tight, and saw off ¼-inch to ⅜-inch above the surface of the work depending on the accessibility. That is to say, a narrow vee should have the studs closer to the work than a more open one.

Second: In welding, the following procedure should be carefully adhered to. Weld around the studs so that they are part of the cast iron; then weld between the studs crosswise or diagonally until the entire surface of the cast iron that has been veed out and the adjacent surface forming the underside of the pad is completely covered before proceeding with the main filling in. That is to say, add metal, one bead at a time, so that no great section of the weld congeals from the molten state at any one time.

First welding the stud to the cast iron makes the stud an integral part of the casting. Welding from stud to stud diagonally or crosswise draws the fractured surfaces together to their original contact, if a small amount of the original break has been left intact at the bottom of the vee. This can be done in most instances; but, naturally, not if pieces are broken out and lost, and must be replaced by a casting or forging. In this steel studding process for cast iron, especially on cylinders and the like, machining is often necessary subsequent to welding, and the hard stratum of metal directly under the weld prevents ordinary cutting operations and grinding must be resorted to. There are other means of taking care of this hardened layer for machining on the surface, one of the newest of which is to finish the machined part with a nickel-copper electrode, which electrode has the property of so merging the cast iron that there is no hard layer of cementite formed. This electrode was developed by the automobile trade for repairing scored cylinders and the like. Older methods are to calk the bottom of the vee, say with copper, which is machined off later. Probably the best method of all is to supply a bushing for the finished part. Many cylinders, especially those of steam engines, are built with this bushing originally; and, in welding, the bushing is to be removed and perhaps slightly refitted after the welding job is finished.

There is no mystery about the electric weld making the cast iron hard at the joint. It is simply that the cast iron is heated up to the welding temperature necessary, and is chilled by the adjacent mass of cold iron. Chilled cast iron has always been hard and probably always will be.

Cast iron differs from steel in containing 3½ per cent. carbon, more or less, whereas steel, even the hardest, contains less than 2 per cent. carbon, and 98 per cent. of all steel in the world has less than 3/10 of one per cent. carbon. The cast iron with the same amount of carbon in it may have the carbon in two forms, i. e., combined and uncombined (graphitic). In the combined form, the cast iron is very hard. In the uncombined form, it is comparatively soft, easily machined and can be calked. Various degrees of hardness range between these two limits according to whether all of the carbon has flaked out of the combination into graphite, or whether some remains in combination. The conditions as to whether the graphite will be separated, or remain in combination, depend on the rapidity of the cooling from a temperature just above a red heat. If it is cooled rapidly, there will be no time for the graphite to come out of combination. If it is cooled very slowly, the graphite will all come out of combination and various degrees of hardness are obtained by different rates of cooling. A form of cast iron called malleable cast iron is less used, in which after weeks of slow cooling, the graphite settles to the outside and is taken off the cast iron, and it begins to take on the properties of wrought iron. As already said, this is a long process, and real malleable iron is rapidly going out of use due to the time taken to make it. So-called malleable iron is generally cast iron with very little of the graphite removed.



In making a weld on cast iron cold, naturally, the cast iron is cooled very quickly, or chilled just below the joint of the weld and sometimes the weld itself will be very hard because of the very quick cooling. This occurs whether welding with a steel electrode or with a cast iron electrode. This chilling, hardening effect can be removed by reheating and annealing in lime or warm sand, or any way to allow it to cool slowly from above a red heat.

To avoid this hardened layer when welding with steel, or to avoid the hardness of the entire section when welding with cast iron, the following procedure must be followed: When the piece is of such shape that it can be welded cold, reheating and annealing will render it capable of being machined. This can be done at any time after welding, by bringing the weld and adjacent cast iron up to a little higher than a red heat and allow it to remain there from two to ten minutes, depending on the size of the piece, then cooling slowly by burying it in warm sand, fire clay or lime. When the piece is of such shape that the cooling strains when welding quickly, as in electric welding, would warp or break the piece, preheating is necessary; however, only to a small degree; that is, less than red heat, in order to save the piece from breaking while welding. Directly after welding, the weld and adjacent cast iron should be heated a little higher than a red heat and annealed as before. This method results in welds made either with steel or cast iron electrodes being easily machined throughout. Welds made with a cast iron electrode are not distinguishable from the original cast iron by either physical or chemical analysis.

In general, cast iron containing small amounts of steel, so-called semi-cast iron (semi-steel), is much easier to weld than pure cast iron.

Generally, the only welding executed on cast iron, except in the case of accidents, is where the original cast iron is defective because of sand holes, porous spots or other flaws occurring during casting. Such sand or slag must be entirely removed before satisfactory welding can be expected.

Usually, the cast iron electrode, while it becomes more fluid than steel under the arc, cools more quickly than steel and from the outside inwards; while steel cools from the inside outwards by the conduction of the heat in the weld

TWO OTHER GOOD EXAMPLES OF WELDING.

into the adjacent metal. Hence with cast iron there is more chance of voids and gas bubbles being left in the weld, and some sort of flux to prevent this is necessary in depositing cast iron; desirable ingredients in such a flux being:

1. A quieting reagent.
2. A quick floater of dross to the surface.
3. A protector against oxygen and nitrogen, so that bubbles, films or needles of oxide and nitride are not left in the weld.
4. Protection against rapid cooling of surface.

The studding of cast iron is not necessary in all cases, for instance:

First case: Simply as a means of filling in, or building out, where grinding is the only machining necessary. Clean out the spot to be welded by chipping or grinding so that all dirty, oily, sandy, or porous metal is cleaned away and a reasonably bright metal foundation is provided for the weld. Weld with either a steel or cast iron electrode according to whether a reasonably hard or a very hard surface is wanted after grinding. The steel gives a hard surface and the cast iron a very hard surface. Care must be taken in using the cast iron electrode that the quick cooling does not entrap gas bubbles in the weld, leaving holes after finishing. The steel causes no such trouble, but if slight imperfections should show, peening will close them up.

Second case: Welding cast iron where tensile strength is required, but not resistance to bursting pressure; such as welding broken machine parts, small bed-plates, etc. In general, where no undue strain will be encountered and the part was originally broken by some accident which will hardly happen again in the same place, proceed as follows: Vee out the break wide enough so that the electrode can be held at approximately right angles to either face of the vee. Cover the two faces of the vee separately with steel, using great care to have the steel united to the surface of the cast iron as the arc progresses, and not to let any of it run down ahead of the puddle. Weld from the bottom up; and, if any of the deposited metal does get away, stop and chip it off. After the two faces are successfully covered, it is extremely easy to make a good weld from the steel faces, using steel or cast iron in the vee.

Cast iron will not endure any considerable deformation. In other words, it cannot be bent, stretched or changed from its original shape in any manner without breaking or cracking. To relieve the stresses, set up in welding cast iron cold, the weld must contract. If the shape of the cast iron pieces is such that one or both ends cannot move with the weld, something must give way. If the weld is one-quarter or less of the section of the cast iron and a good joint is made to the cast iron, the weld will hold; because the weld, even if of steel (the steel being four times as strong as the cast iron) will stretch if it is one-quarter or less in area. However, it does not hurt the weld to stretch. It is similar to working steel after casting into forgings and rolled shapes. If the weld can be put on a little at a time, so that its cross section is also less than one-quarter of the cast iron which it is welded to, results can be obtained which will not bend out of the original position, even on a section that is ultimately the same size The foregoing applies to welding with steel electrodes. In welding with cast iron electrodes, the relative strengths would be the same, but due to the cast iron weld not being able to stand any deformation, it would crack through the weld. The remedy for this is to preheat the parts to be welded so that they will all contract at the same rate. In this manner, welding with a cast iron electrode is much more rapid and more satisfactory than any other process. The arc has a tendency to burn out the carbon in any weld, and this is especially true where the carbon approaches 3½ per cent. There has been developed a coating for the electrodes which replenishes the carbon, so that true cast iron of the same nature as the original results in the weld.

There is another method which has a basic theory similar to studding, and is especially useful for sections that are too thin to stud; that is, automobile cylinders, jackets, crank cases, heating boilers, and other cast iron parts complicated in shape, and which can tolerate no deformation. This is to run beads at right angles to the crack about eight to ten times the thickness of the weld at the crack, with right angle beads laced back and forth at intervals of four to six times the thickness of the piece to hold the weld and adjoining cast iron from separating; so that the contraction takes place in the weld where it does no harm. In this manner automobile water jackets, crank cases, furnaces, etc., have been welded. Automobile water jackets have also been welded in emergencies without taking the water out of the engine. Sometimes the weld will be stressed beyond its elastic limit and crack, but no precautions need be taken in regard to rewelding, as this crack will then have steel to hold it. Naturally, the less heat used, the less will be the stresses to be taken care of. To that end, use the light work taps on the welding machine to secure as little heat as possible. Proceed by welding a little at a time, allowing one bead to cool completely before beginning the next one; except in the case of filling in the beads at right angles to the weld, which bead should be put down as nearly as possible at the same time in order to fill in the spaces between the intermediate crosswise of the crack beads. In pieces that have cracked and sprung apart and should be brought into alignment, this method of crosswise beading, proceeding from the smallest end of the crack, will bring the original pieces into such intimate contact that it is very often water-tight before starting the intermediate beading. In order to keep the heat as low as possible, a special electrode, whose melting rate is higher than ordinary steel, should be used. You will find this will aid materially in keeping the stresses down. All of this welding with steel is done without preheating or annealing of any kind, the necessary finishing being done by grinding. I know an operator who has not seen anything but cast iron welding for so long that he probably has forgotten how to weld steel, and the majority of cast iron work in a jobbing shop can be done without studding. In cases of scored cylinders, if the machine can be set so that it will draw an arc, but not sustain it, the metal can be deposited in one flash at a time; without cracking the adjacent cast iron, by using a special nickel electrode. In the case that the machine cannot be set at half-voltage, a foot switch in the secondary circuit or the primary circuit should be opened, as each drop is deposited so as not to use the high heat in depositing the metal. If a nickel electrode is used, the weld must be calked in place, but a special electrode of nickel and copper can be run continuously, providing the cast iron wall is thick enough to stand it.

To sum up: cast iron welding with the electric arc is to my mind just as useful as with gas and a great deal quicker and cheaper when the parts are preheated. Also, as pointed out in this paper, there are a great many places where electric arc welding is possible without the trouble of preheating and often where preheating would not be possible.

---

## IMPORTANT DATA BOOK.

The Hamilton Gear and Machine Co., Toronto, Canada, have issued a valuable data book on gearing that will interest plant owners and designers generally. It contains formulae, tables, and gear data that are in constant use in their own plant, therefore in constant use throughout the country. The matter has been placed in very convenient and condensed form, and gear users can find in these pages brief, yet accurate gear information.

The object of the book is first stated, then follows the information necessary to quote on, to cut, or to supply gears. The form of gear teeth is next taken up, tables being given for pitch diameters of various diametral and circular pitch gears. Tooth parts follow, then standard size of keyseats for gears. Correct method of inspecting gears is also shown, and rules and definitions of gear teeth generally are stated.

### Bevel Gears.

Next comes the rules and definitions for bevel gears, this data being carefully explained. The method of cutting bevel gears is shown. Tables of diameter increments follow, also information on double helical gears; worms and worm gears; standard worm gear reductions and miscellaneous types of gearing.

Rawhide pinions the next discussed also method employed in the heat treatment of gears in their plant. The materials from which gears for various purposes are made; limits of tolerances on holes; shafting sizes; strength of gear teeth; table of sizes,cosines, etc. also pattern proportions follow in sequence. Various other valuable tables complete this data book of 48 pages.

A limited number of these books are being sent to their customers, but for general distribution the price is 50c which is hardly half the actual cost of production.

## ERRATA

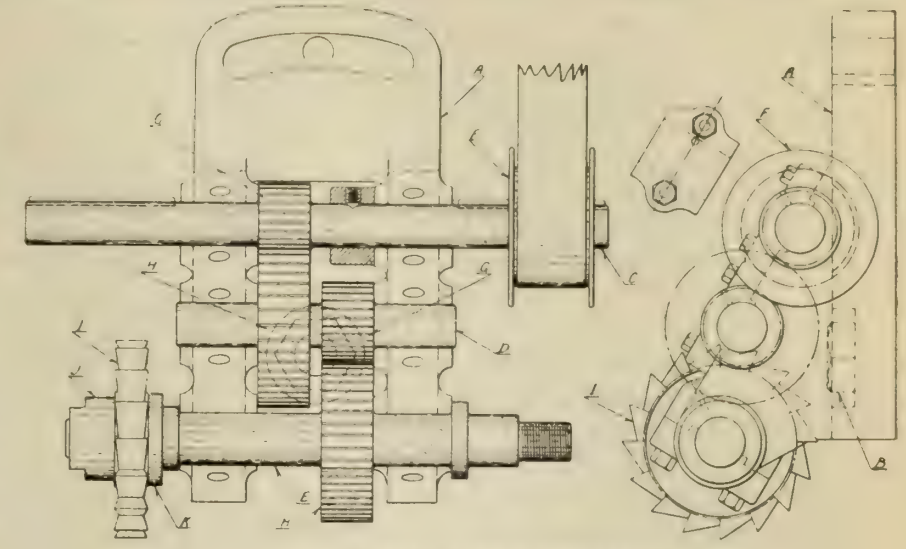
On page 97, May 26th issue of Canadian Machinery, under the head of "Punch and Riveter," it was stated that this was a new product made by the Band Pneumatic Tool Co. This was an error on the part of the printers, a Baird Pneumatic Tool Co., Kansas City, Miss., was what was intended.

## LOCOMOTIVE STAYS.

(Continued from Page 41).

releasing the plunger from the notch and permitting the turret to be withdrawn. This leaves the cutting off tool in proper position for parting off the stay.

Copper stays 1 inch diameter and 6½ inches long are machined in this manner in 40 seconds. The attachment we have described is equally suitable for producing mild steel stays, the tool layout being exactly the same. The operation time on a mild steel stay 1 inch diameter 7 inches long is 2½ minutes. The attachment carries a 1 inch die-head, and threads stays up to 1 3-16 inches diameter, if required.



# WHAT OUR READERS THINK AND DO

## ILLING KEYWAYS ON A PLANER

By J. H. R.

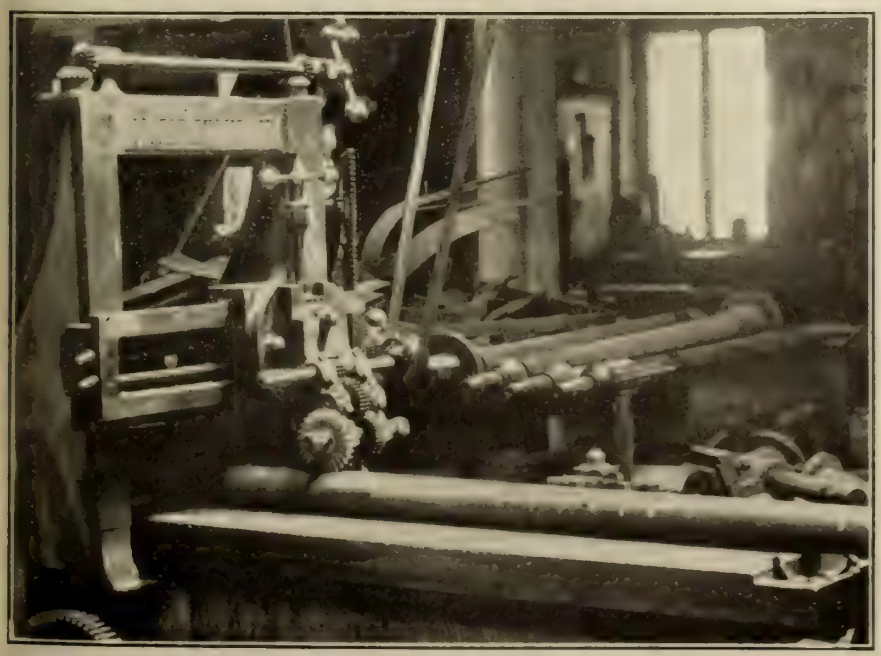
The device shown is one that is in e for the milling of keyways and sim- ır work when a regular milling ma- ıine is not available. As can be seen om the illustration the attachment is ·ld in the tool head of a planer and the ork clamped to the table of the ma- ıine. For feeding the work to the cut- r a feed screw is arranged on the oper- ing side of the machine, the feed ındle being shown beneath the right ınd end of the table. Supporting ·ackets are secured to the planer bed, hile one with the feed nut is fastened the side of the table by means of the ·dinary T-slot. The line drawing shows ıe design of the milling head. The ›dy of the head A, is bolted to the regu- r tool head by means of the pivot stud and the upper clamping nut. The rimary drive shaft C is extended on ›th sides of the head so that the drive ulley F, can be located on either end suit working conditions. The two- rive pinions G G, are integral with their ·spective shafts, while the gears H H, re keyed on. The cutter shaft E, is rovided with solid collars to take end ırust. Cutter I, can be placed on either nd to meet work requirements. The ountershaft is provided with a drum to ccommodate varying locations of the illing head.

DETAIL VIEW OF THE MECHANISM.

## ROLLING MILL ENGINE.

(By Earl R. Tindall).

In the May 19th issue of Canadian Machinery, Page 52, I noticed with interest the description of a rolling mill engine, at present being completed in a British steel works.

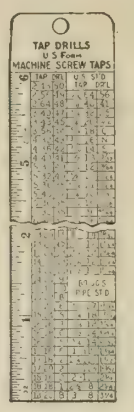


I am very much interested in steel mill news as I was four years on a forty-inch blooming mill at Cleveland, Ohio, and rolled on this particular mill during the last two years of the war. The engine that ran the mill was built by the Mesta Machine Co., and was purchased as a 35,000 H.P. engine, although when tested it actually developed 37,000 H.P. It was a twin tandem compound, with two high pressure cylinders 46 in. diameter, and two low pressure cylinders, each 76 in. diameter, the stroke being 5 feet. It took a good sized train of flat cars to bring the engine from Pittsburgh to Cleveland to be assembled on its foundation.

It was a one lever engine, and by this I mean that the throttle and reverse levers were one and the same. The throttle valve was opened and closed by a steam jack, and the steam could be shut off by electricity at any time the engine got beyond control of the engineer.

To give readers an idea of the speed with which the engine could be reversed, I might mention that I have seen eleven three-ton ingots rolled in ten minutes, giving each ingot seventeen passes through the rolls, reversing at each pass.

The record for fast rolling on that mill when I left two years ago was 158 tons of slabs in one hour. These were rolled from 5 ton ingots; three inch draft to an ingot, that is taking off three inches in one pass, through the rolls was a regular everyday pull for this engine. I think readers will agree with me that the engine I speak of was "some engine," although there is one of the same type and size at Youngston, Ohio, while there is a still larger one in Gary, Ind.



This is the type of chatty information we always like to receive. The letter from the above writer was unsolicited, and shows clearly he enjoys perusing his Canadian Machinery.

GENERAL VIEW OF THE ATTACHMENT.

# Improve Your Powers of Perception—Try This Contest

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

J. A. Scarsbrook, 307 Popular Ave., Winnipeg, had the only correct list for the May 26th contest. Several readers complain that they send in correct lists, which we don't acknowledge. This we can readily explain. When we do not announce a list correct, it is because the list never reached us. As it is, some of the answers sent in reach us by good luck. For example, one came to the office to-day addressed McLean Publishing Co., Toronto. Considering the fact we have numerous papers being published, it is wise to always mark your envelope as follows: "Canadian Machinery Contest," Editorial Dept., 143 University Ave., Toronto. If this is done there will be no further difficulty.

**CONTEST FOR JUNE 16TH ISSUE**

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1—Something that not everyone will agree on
2—A product accurate in two important points
3—How to cut expense in six.
4—How to get away from lumber expense
5—What to do if a tap breaks.
6—Something said to be air tight under all pressures
7—A line of products that are all guaranteed
8—How to get continuous, efficient service
9—A case where inspection isn't everything
10—How to boost production 50%
11—What to use on heavy engines.
12—How to get a check on accurate work

**These are Correct Answers for List from May 26th Issue.**

1—Pratt & Whitney Co. of Canada.
2—John Bertram & Sons Co., Ltd.
3—Oakley Chemical Co., per C. P. Murphy.
4—Cleveland Pneumatic Tool Co. of Canada.
5—Hoefer Mfg. Co.
6—Canadian Ingersoll Rand Co., Ltd.
7—Canadian Fairbanks-Morse Co., Ltd.
8—International Malleable Iron Co., Ltd.
9—Chamber of Commerce, St. Catharines.
10—National Acme Co.
11—Modern Tool Co.
12—Cincinnati Electric Tool Co.

## Closing Date for This Contest is July 7th

# DEVELOPMENTS IN SHOP EQUIPMENT

### NORTON AUTOPART REGRINDING MACHINE.

The Norton Company, Worcester, Mass., has just placed on the market a special type of grinding machine designed for automobile regrinding shops. This machine is so arranged that the various set-ups required on this class of work can be very easily and quickly made. It is adapted for the regrinding of crankshafts as well as the grinding of pistons, piston pins, valves, etc. With a swing of 18" and a distance between the centers of 55" it will accommodate practically all makes of crankshafts. With the 12 work speeds provided, efficient grinding can be performed on work of small as well as large diameter.

The base is heavy and rigid, and is supported at 3 points. This method of support makes it unnecessary to provide special foundations for the machine, and insures permanent alignment. The wheel slide is of massive design, weighing about 900 pounds, and is equipped with 26" diameter grinding wheel so that ample clearance will be provided when grinding crankshafts for long stroke motors. The headstock and footstock are of standard Norton type except that they are somewhat heavier and have longer bearing surfaces on the table. Large capacity pump is supplied which is driven directly from the overhead works. The standard wheel feed mechanism is used, consisting of 3½" diameter feed screw engaging with half nut underneath the wheel slide. The wheel slide rests on one flat and one vee way. These ways are of such proportion that the slide practically floats on a film of oil.

The precision of this machine may be judged by the fact that the movement of the feed index pin one space advances the 900 pound slide exactly one eighth of a thousandth of an inch. The table is operated by a two-speed hand feed apron. In order to provide for the many types of crankshafts which the regrinding shop handles, a very simple adjustable end block is furnished with the machine. With these types of blocks no bushings or other devices are required for fastening different diameters of shafts in the fixture.

There is also furnished with the machine as part of the regular equipment a combined center and valve face grinding attachment. By the use of this attachment, the machine centers may be re ground and kept in perfect condition. The attachment is adjustable, permitting the regrinding of the faces of all types of valves. On account of the various features incorporated, this machine will handle all the cylindrical grinding necessary to put an engine in first-class condition. It is claimed that this machine together with a cylinder grinder constitute all the grinding equipment necessary for a shop doing this class of work.

Following are the specifications:—Length between centers 55", swing 18", weight of handstock 240 lbs., range of work speed 20 to 207 r.p.m., weight of footstock 100 lbs., weight of wheel slide 900 lbs., length of bearing ways 24½", length of spindle 28¼", large bearing 3½" diameter, 8" long, small bearing 2" diameter, 6" long, diameter grinding wheel 26", net weight of machine 7,600 lbs.

---

### SHEAR BLADE AND FACE GRINDER.

The Springfield Mfg. Co., Bridgeport, Conn., has placed on the market a heavy duty reversing motor shear blade and face grinder.

This machine is entirely self contained, operated by three motors; one of 15 H.P. for driving the wheel; one variable speed 5 H.P. reversing motor for driving the table traversing mechanism, and one ½ H.P. motor for driving the pump. The variable speed motor permits of obtaining a table speed of from 7 to 27 feet per minute, and the reversing feature of the motor dispenses with belting. The operation of the machine is controlled from either front or rear by mechanical means, and is also provided with a push button for controlling the motors. The machine has a wheel 24" in diameter and has capacity to grind 12 ft. long, but is made in lengths varying from 6 ft. to 17 ft.

This machine can also be furnished with a swivel knife bar, making it suitable for grinding large paper and veneer knives, and by removing an angle bar it becomes a standard face grinder and can be used for all kinds of grinding within its capacity. Special bearing construction is used, this being known as the sleeve flange type, which fit into bored holes and bolted in place by a flange. These are again bronze bushed and can easily be replaced in case of wear, the original alignment not being disturbed.

The machine is of very heavy construction, carrying two wheels 20" diameter, 6½" wide, on a spindle of 3½" diameter; the spindle operating in bearings 3½" diameter by 18" long.

One of the principal features is its direct motor application to an oscillating motion of the spindle, and this is accomplished by using a drum on the spindle and holding the belt stationary, the drum pulley being connected direct to the spindle, and with the oscillating slides. The whole mechanism is oscillated back and forth by means of a crank motion on the right hand end of the cross rail slides.

## An Unusual Action

IT is reported from Springfield, Mass., that the members of the Machinists' Union, of their own free will and accord, have accepted a reduction of 12% in wages. According to the report absolutely no pressure was brought to bear on them by the employers. The decision was arrived at in a secret meeting of the men, and became effective immediately. There is a considerable reduction in the working time of most of the factories in the district, and those that are working full time are doing so with considerably reduced staffs. It will be interesting to note the effect of the action taken by the Machinists' Union. Not being a productive branch in one sense, it may not have a very great effect on manufacturing firms as far as increased activities are concerned, but it may indirectly do a great amount of good in the direction of carrying out much needed repairs, and in some cases new installations. Lower wages to machinists means a lower cost of many articles of equipment, and should have a stimulating effect. If manufacturers are enabled to buy equipment that they have been delaying the purchase of due to high prices, they will be in turn enabled to reduce their production costs, which will stimulate sales, and thus give increased employment. Such action as that taken by the Springfield machinists if emulated by others would speedily make a difference in the present time of watchful waiting.

## Raising the Rates

IN another portion of this issue we refer to the movement which has been started by the railroads to elevate the listing of machinery from sixth to fifth place. Not only is a higher freight rate suggested, but the proposal contains an increase in the minimum of carload capacity from 20,000 to 24,000 lbs.

This tentative suggestion is primarily advanced for the purpose of increasing the carrying tonnage of freight traffic. Canadian Machinery, discussing the subject with various dealers, finds that according to those interested, no more machinery can be shipped than what the market periodically calls for.

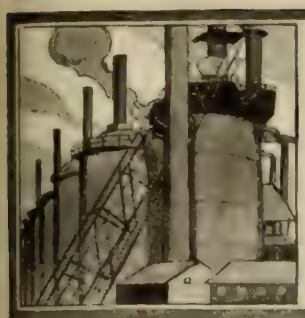
As a general rule current orders are of small weight, with as occasional purchase of six to seven thousand pounds. At present dealers try to combine these shipments in a given direction, accordingly to locality, in order to secure the carload rate, and of course at the same time obtain prompt delivery. As a rule, the total tonnage is well below the 20,000 lbs., so that should this suggestion of raising the minimum go through, any such increase in rates would most likely be reflected in the cost of the machines to the consumer.

It seems to be the opinion of the trade generally, that the adopting of such a measure would inflict an additional hardship on the machinery business. This is a time of declining prices, not a day for increased costs, and those responsible for the deciding of this matter should weigh carefully the result it would have on business before giving their decision. Railway revenue is important, but on the other hand business interests must not be strangled to produce such revenue.

Marnet Summary, 3-column head

## Aerial Photography

THE strides made in the art of Aerial Photography within the past few years have been nothing short of marvellous. Before the war this art was in its infancy, in fact was practically unheard of. During the war its development was rapid. With a camera, the observers could come back, not with a mere descriptive story of what they had seen, but an actual reproduction of the ground they had passed over. The value of such records can never be fully realized.



This style of photography has also opened up many new fields, including the photographing and mapping out of industrial plants and grounds. There is an old saying that photographs cannot lie, and the prints made from photographs taken from above show plainly all scrap piles littered grounds, and poor arrangement of piled material Such photographs are also useful when planning extensions The use of this type of photograph in many cases saves expensive surveys, and the art is sure to still further advance as new uses are discovered.

## Rules for Industry

THE commission which has been studying the economic situation in Belgium, has brought out some fine points many of which could be studied by Canadian manufacturers to advantage. Among the recommendations made by this commission are the following so-called industry rules:

To market cheaply industry must be improved by the most modern technique, and the most up-to-date improved machinery. In organizing the industries, specialization and standardization needs must be taken into account, and the mechanism must be designed and adapted to meet these requirements. Industries and manufacturers are advised to combine for the economic handling of credits, and so on through banks and export agencies, acting for the collective interests of all. Appeals should be made to agents of industry and well-informed workmen for increased production, and, in addition, methods of remuneration that will incite workers to produce more should be applied. To avoid conflicts with workers, committees of employees should be set up to control the internal or domestic mechanism of the industry.

By following these recommendations Belgian industry has already made notable strides toward recovery. The lesson may well be followed by industry in other countries

# MARKET DEVELOPMENTS

## Improvement Shown in Number of Enquiries

### While there is Not Much Change in Business, a Better Volume of Enquiries Are Present. Railways Attempt to Raise Classification of Machinery. Scrap Market Weak.

THERE is in evidence this week a much larger volume of enquiry, from which some dealers deduce a change for the better, but others seem to consider but a flash in the pan. There has been no change in prices, in the machine tool trade, and the chance for improvement in the immediate future is not any too good. The next month or two is at the best of times a dull season, and there is no reason to think it will be otherwise this year.

One feature is the large number of small orders that are in evidence, and although the volume of business transacted through these orders is small, it keeps the staffs just as busy as large orders would. Local steel warehouses report a good volume of inquiry this week, in fact better than for some time past, and this is considered to be in some measure encouraging. However the amount of business that will transpire through the inquiry is doubtful.

The steel mills of the U. S. had a somewhat larger production in May than in April, and this is credited almost entirely to the operaton of the independent mills. The Steel Corporation ran at less capacity in May than in April. Production has been dropping steadily since the latter part of May and the average over the independents and the Corporation is not more than 25% at the present time; and it is expected to get as low as 20% before the end of this month. The falling off in production is due to an absolute lack of buying by any of the ordinary consumers of steel, and reduction of prices does not help in any way to stir the interest of the consumer. They simply do not want to buy under the present conditions.

Pig iron under these circumstances, is naturally at a very low ebb, and further small declines have been noted, but it is not expected that they will go any lower unless there is also a drop in freight rates and production costs in general.

The scrap metal market is very quiet, and local dealers report no change in the situation. There are pretty heavy stocks on hand, and a tentative reduction in prices did not bring forth any eager buyers. Reports from the different U. S. centres tell about the same story.

## THE STEEL MARKET IS IN PROCESS OF HAVING STILL ANOTHER DECLINE

Special to CANADIAN MACHINERY

PITTSBURGH, June 16.—From the monthly report of the American Iron and Steel Institute, giving the steel ingot production of 30 steel companies, the indication is that the steel industry as a whole produced steel ingots at the rate of about 18,000,000 gross tons a year in May, or at about 34 per cent. of capacity. The April production was at the rate of about 32 per cent. of capacity. The increase was due entirely to heavier operations by independent producers, who operated at about 25 per cent. of capacity in April and at about 32 per cent. in May. Estimates are that the Steel Corporation ran at about 41 per cent. in April and at about 38 per cent. in May.

The increase in operations by the independents was due to the extra business they gathered up in April at the time they were advancing their prices, as they gave customers an opportunity to cover at the former prices. The announcements of advances began about April 8, while it was on April 12 that the Steel Corporation announced its reductions, to the levels to which the independents had just advanced, the condition of the independents having much lower prices than the corporation then ending by an equalized market being established, though this was largely on paper since for a couple of weeks afterwards there were reports of independents getting business at "old prices" as it seemed to be difficult to recall all the quotations outstanding.

This burst of activity was followed by a lull, since the independents soon finished most of the business they had booked, and fresh sales were very difficult to make. Since the middle or latter part of May operations have been decreasing, and this week operations may be estimated roughly at 15 to 20 per cent. for the independents and at 30 to 35 per cent. for the Steel Corporation, making an average for the whole industry of not over 25 per cent., this comparing with averages of 34 per cent. in May and 55 per cent. last January.

Judged by the present rate of buying, which is smaller than was previously thought possible, steel production is likely by the end of the month to be down to a rate of 20 per cent. or less. A 19 per cent. rate would mean 10,000,000 gross tons of steel ingots a year, equal to about 160,000 net tons of finished steel a week. Some observers express the opinion that scarcely any steel at all will be made in July, except for very special purposes.

### Stocks of Manufactured Goods.

The almost complete stoppage of buying of steel from the mills is attributable to a variety of influences, as the buyers of steel fall into different classes. The railroads, whose natural requirements, however, have been generally overestimated in recent years, have no money and little credit, while with a good supply of funds they would hardly spend freely when on account of costs the money would not go far. As to buyers of steel for construction work, the erection of bridges, hotel and office buildings, factories, etc., the investors consider costs of construction too high, they would have to pay too high interest rates on borrowed money, and they are doubtful of the earning power of investments in the near future.

The third important class of steel buyers is the so-called "manufacturing consumers," making hardware, hand tools, machinery, agricultural implements, etc. These buyers are not all in precisely the same position, but the common position is that they have large stocks of their manufactured goods, which are not selling, hence they do not wish to manufacture more. They have some stocks of steel, which they would like to reduce. In general the desire to reduce stocks of unmanufactured steel is not due to the stocks being large in relation to normal consumption but to operations being so light that the factories do not want to

carry normal stocks of their raw material. Steel salesmen relate that often when they call on a customer, the customer, instead of considering the purchase of steel, asks the salesman if he cannot sell some steel for him.

For several months there has been much talk of there being a "buyers' strike" and this view is largely correct even at the present time, though the mental attitude has changed somewhat. It is no longer a mere strike against high prices, for buyers have reduced their views as to how much they would buy if the prices were satisfactory. It must be understood also that in the case of the steel mills it is not a strike of their direct customers for lower prices for steel. If that were the case the mills would be glad to come to terms. There are no terms offered. The agricultural implement maker, for instance, does not tell the steel mill he would buy steel bars if the price were so-and-so instead of 2.10c. He shows the steel salesman his large stock of implements, filling his warehouses, and says the farmer is not buying.

### Steel Prices.

The steel market is in process of having another decline. The decline will cover some period of time, not being in the form of one clear cut set of reductions. How long the process will take, and how far it will carry prices, no one can predict. All that can be said is that the decline has begun. A fortnight ago, when most of the independent wire mills had been selling nails at $3, against the April price of $3.25, the Steel Corporation began to meet the cut price, and since then plain wire has dropped $5 a ton to $2.75 and galvanized barb wire by the same amount, to $3.85. In plates there have been sales, even in small lots, at $2 against the April price of $2.20. Bars and shapes have shown little shading as yet, while there is considerable shading in sheets. The Steel Corporation will meet independent cutting on most products if not all, but only when the cutting becomes widespread, and thus far does not seem to have reduced on anything but wire products. The Corporation will not hold aloof from independent cutting as it did in February and March.

This report of a week ago ventured the guess that the present decline will run to something like $10 a net ton before a clear cut market is established again. No closer guess can now be made. There is no likelihood that there will be a full return to the pre-war average of prices, much less to the low point before the war. Nothing like full operation of the steel industry is expected by anyone this year, and with light operation costs are high, because the overhead is poorly distributed and because it takes much more labor per ton of output when a mill is running light than when a mill is running full. Some mills will prefer to take their loss by being idle entirely than by running part time, hence prices cannot go down indefinitely.

### Pig Iron.

Pig iron prices continue to sag, but the declines are now by small amounts, showing that the market is beginning to scrape bottom, on the basis of present freight rates and present wage rates at the coke works, limestone quarries, ore mines and blast furnaces. If freight rates and wages come down the bottom will be lower. Basic iron is quotable at $21.50, valley, or 25 cents decline, and foundry iron at $22.50, or 50 cents decline. Bessemer remains at $23, valley, a market price developed on sales of single carloads.

## POINTS IN WEEK'S MARKETING NOTES

**Enquiries are somewhat better, although there is some indication that the steel market is in process of another decline. How long it will last, or whether it will affect prices much is not known.**

**Since the latter part of May, operations in the mills has been decreasing, and this week's operations may be estimated roughly at 15 to 20 per cent. for the independents, and at 30 to 35 for the steel corporation. This makes an average for the whole industry of about 25 per cent. against 34 per cent. in May and 55 per cent. last January.**

**Pig iron prices continue to sag, but by very small amounts, showing that the market is beginning to scrape bottom. Basic iron is quoted at $21.50 valley, or 25 cents decline, while foundry iron is marked $22.50 or 50 cents decline. Bessemer remains at $23.00 valley.**

**Prices in old material have weakened considerably since last week. This is due to a falling away in demand. Indications are that things will not be better for some little time.**

**The recent price slashing by automobile builders, and a general business stagnation have had their effect on the iron and steel scrap market at Detroit. The general tone there is far from promising, and business as a whole is much below normal. Wrought iron axles are down to $24.00, heavy melting steel being quoted at $7.50, which is a slight increase, due to a sudden demand. This however, is not expected to last.**

**The railways have started a movement for increased rates. It is suggested that the minimum carload weight be raised. Dealers claim that if such an arrangement goes through, it will affect the price of machines generally.**

**Prices in the machine tool business remain much the same, and general conditions are reported to be practically stationary.**

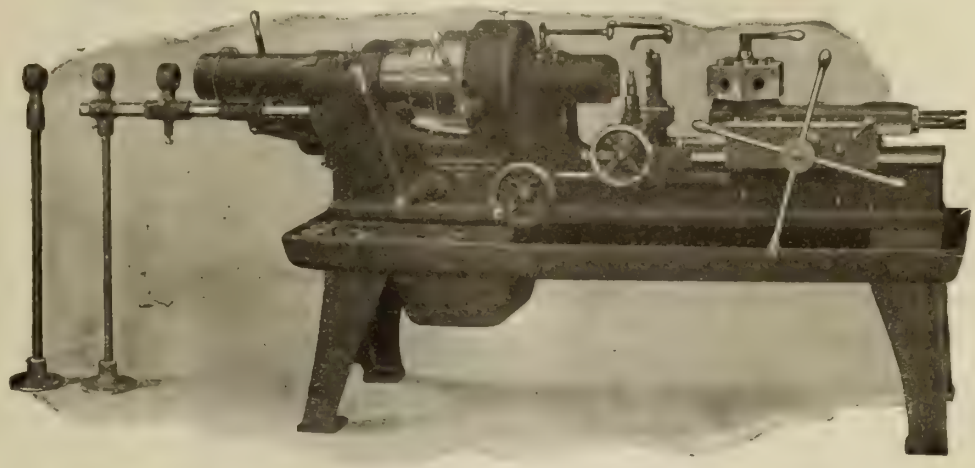
## NEW MOVE ON PART OF RAILROADS

**Railroads Want to Raise the Listing of Machinery From Sixth to Fifth Rate. Enquiries are Larger.**

TORONTO.—A movement is reported on foot for the railways to elevate the listing of machinery from sixth to fifth rate. Not only is a higher freight rate suggested through these sources, but the proposal contains an increase in the minimum of carload capacity from 20,000 to 24,000 lbs.

While this tentative suggestion is primarily advanced for the purpose of increasing the carrying tonnage of freight traffic, yet dealers point out that no more machinery can be shipped than what the market periodically calls for. Current orders are principally of small weight, with an occasional purchase of from six to seven thousand pounds. The present method of delivery is to combine shipments in a given directon, or accordng to locality, in order to secure the carload rate and automatically obtain prompt delivery. Most frequently however, the total current tonnage is well below the 20,000 lb. minimum heretofore in effect, and any movement to raise this minimum would result, it is said, in adversely affecting the cost of delivery.

Such an increase would have to be reflected in the cost of machinery to the consumer, which, it is further pointed out, is in direct variance to public opinion and the general trend of prices at the present time. The opinion in the trade seems to be that no increase in carload-carrying capacity can be achieved in this manner, and that such revised regulations would fail, if that is the chief objective. On the other hand, to increase the railway revenue through this adoption would inflict an unexpected hardship on the machinery business. Dealers state that they can and always have arranged to absorb the extra proportionate cost between the 12,000 or 14,000 lbs. that is loaded into cars under current methods, and the charge for the minimum of 20,000; but any additional charge in this direction would serve to decrease the ratio of carload shipments. The final outcome of the proposal both as regards the higher listing, and also the increased carload minimum, is awaited with keen interest.



Market conditions remain about the same, with a larger number of inquiries now evident. The opinion is expressed that these are probably feelers to test out the market tone. Other dealers state that business shows signs of improvement. While a brisker movement has been noted, it is yet too early for the market tone to register permanent strength. The current business is looked upon as a momentary spurt, with another slackening off apparently due later on.

In the machine tool business, prices are remaining unchanged, and general conditions are reported to be practically stationary. Very little improvement, if any, is expected during the next few weeks, but a more optimistic tone is developing in trade relations. Another dealer reports current markets quiet. A dull outlook is claimed for the ensuing summer months. Plants are mostly working short time, very few running to full capacity. A decrease has been noted, according to this report, in prevailing business, but the heavy proportion of small orders keeps dealers' staffs almost as busy as in a strenuous season. Slightly better con-

## Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

### If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. **Ask us.**

***We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.***

ditions are looked for to prevail during the fall, due to the improved tone of commercial activity, and the harvest period stimulating economic conditions.

Seasonable inquiries are the feature of the steel market this week. The best week in inquiries is reported for some time past, but what proportion of business will result is difficult to estimate. Based on this general surface improvement, prospects are considered a little brighter, for it is encouraging to receive inquiries in this volume. Mill conditions are still varied, however. On the other hand, this week's business is described as another brief spurt, with a reaction expected as soon as current demands have been filled. No price reductions have been announced, but it is practically conceded that better prices could be secured on large orders, if there was a generous volume of business apparent. Every order can be said to be treated on its individual merits, with basic quotations for small purchases, which predominate. No marked development in steel business is anticipated for several weeks.

## Pig Iron Markets

In the 31 days of May, pig iron production was 1,221,221 tons. For a smaller output in a 31-day month, almost thirteen years must be retraced, July, 1908, showing 1,218,129 tons. Thirteen furnaces were blown out in May and seven were blown in—a net loss of six.

The only important business recently done in the Pittsburgh district has been the purchase by an Allegheny Valley sheet maker of approximately 2,000 tons of basic iron at delivered prices of $22.25 to $22.50. One lot of 500 tons of basic iron recently was sold at $21, Valley furnace, and this now measures the market on this grade, especially in view of the fact the merchant producers have expressed a willingness to take business at that figure. The market on No. 2 foundry iron is quotable from $22.50 to $23, but the latter is more of an asking than a selling price.

On the Chicago market a local furnace has sold $1,000 tons of basic iron to a melter in the St. Louis district at $20 base, Chicago. Current business in Chicago and vicinity has been light and largely confined to carload lots. A Michigan melter bought 500 tons of foundry for delivery within the next 45 days at $20 base, Chicago. Locally buying will probably be stimulated somewhat as a result of the settlement of the strike of union molders.

The pig iron market at New York has descended to new depths of dullness. The New Jersey melter which was mentioned as being in the market last week for 1,200 tons has withdrawn the inquiry and will buy from month to month to meet its requirements. The New Jersey inquiry brought out some low quotations, for example, a Buffalo furnace quoted $22 furnace for iron analyzing 1.75 to 2.25 silicon.

The largest sale reported on the Cincinnati market was of 200 tons of Northern iron to an Indiana melter. A Kentucky melter is in the market for 500 tons of Southern iron and 250 tons of either Northern or Virginia iron for June shipment. The National Cash Register Co., Dayton, Ohio, has sent out an inquiry for 320 tons half Northern and half Southern and a central Ohio melter inquired for 500 tons of malleable but almost immediately withdrew the inquiry. With these exceptions the market is very quiet.

The market at Cleveland is dull and weak, foundry iron prices having declined at least 50 cents per ton, to $22.50 for No. 2, at which some small lot sales have been made. A few furnaces, however, are still asking $23.

About 2,000 tons of pig iron was sold by Buffalo furnaces through their several offices at the $24 and $25 base prices, but on the whole business is quieter. Sales are mostly for carload lots and the improvement hoped for by several furnace interests has failed to materialize.

Following a sale of 300 tons of No. 2 plain iron to a radiator plant at Trenton, N.J., at $23 furnace, and Eastern producer of pig iron decided to advance its price to $24 base, with $25 for No. 2X and $26 for No. 1X. Other Eastern producers intimate that they also will adhere to these prices, which constitute an advance of $1 on No. 2 plain from the low point, 50c to $1 on No. 2X and about the same amount on No. 1X.

The St. Louis market might be said to be entirely without feature. The expected activity as a result of the settlement of the stove molders' scale, has not developed and in one or two instances stove molders have asked that shipments under contracts be deferred on account of the condition of their yards.

## Scrap Metal Markets

Prices on old material have weakened considerably since a week ago at Pittsburgh, due to a further falling away in the demand in keeping with steel works operations. Plants in operation appear to be congested and permits for shipments to them are being withheld. Shipping instructions are lacking to those plants which are down or nearly so. Owing to this condition prices have been cut from 50 cents to $1 per ton in almost all grades. One steel maker was recently offered 1,000 tons of heavy melting steel at $13 delivered, but being filled up for the present refused the offer.

The indications in the scrap market at Chicago are that prices will be lower and quotations on several grades have declined about 50 cents during the past few days. Prospects for moving scrap are less bright and this is reflected in the attitude of dealers.

Trading in scrap has been listless during the week at Boston. The stiffening tendency in the market that existed during the latter part of May has in several instances appreciably stiffened. Machine shop turnings have dropped from $3 to $2.50 and car wheels, No. 1 machinery and skeleton scrap are weaker than they were several days ago.

New York reports heavy melting steel and machine shop turnings as being easier, now holding at $7 to $7.50 and $4 to $4.50 f.o.b. New York. Other grades are nominally unchanged although weakness is in evidence throughout the market.

Outside of a few scattered inquiries for heavy melting steel, the scrap market continues weak for every grade. A little miscellaneous buying is being done with the market still holding at $13.

Price slashing by automobile builders and a general business stagnation have had their effect on the iron and steel scrap market at Detroit. The general tone is far from promising, and business as a whole is much below normal. Wrought iron axles are down to a ne low, $24, and heavy melting steel, d to a slight increase in demand duri the last days, is quoted at $7.50.

### CROSS INDEXING MECHANICAL I FORMATION.

(by F. M.)

A very convenient method of indexir miscellaneous information, such as usually accumulated from catalogue notes and magazines, is shown by th accompanying chart. This chart may b used where the information indexed placed in regular letter files, cabine or most anywhere that a letter of nun bered system is used.

Referring to the chart it will be n ticed from the title that this index r fers to "File number 1," from Janua 1918, to a date which is to be filled i when a new index sheet and addition file is developed. Below the title in th diagonal spaces are major titles suc as Lathe, Milling, Planing, etc. In th column at the extreme left are a nun ber of sub-titles. Intersecting lines ru ning from both of these titles for spaces in which letters or numbers a placed and reading down from one co umn along the top and across from column on the side; by noting the lett in the space which they form whe they intersect, it is apparent that th subject matter so designated is file under that letter or numeral.

For example, we will presume th it is desired to look up information th has been accumulated under "Adve tising Forms." Looking along the to we find the word "Forms," and glancin down the left hand column we find "A vertise," while in the square where th two intersect, is the letter "V." O would therefore look into the file "V for the information desired; likewise it was desired to find information in r gard to drilling machines, one wou look along the top to the word drillin along the left to the word machines, a at the intersection of the two is th letter K indicating the file to be looke up.

A chart of this nature can be easi compiled to suit individual requiremen and may be more or less extensive. can be pasted on a card and makes very handy visible index.

## NEW SHOPS, TENDERS AND CONTRACTS PERSONAL AND TRADE NOTES

A new plant has been opened up at the corner of Queen and Wellington Streets, Kingston, Ont., by Mr. R. M. Campbell. A $4,000 Heald Cylinder Grinder has been installed and the plant is ready to handle all worn and scored cylinders for all machines.

The new bridge which has been built across the Red River at Morris, Man., was opened for traffic on June 2nd. This bridge was built at a cost of about $140,000 and is by far the largest highway bridge in the province. It is 606 feet long and the main span measures 368 feet. The bridge is unique in respect of its being the first fixed span over the Red River.

The Hamilton Bridge Works, Hamilton, Canada, one of the biggest manufacturing concerns in that city, has closed down for an indefinite period, owing to slump in trade. The employees were advised to look for work elsewhere.

Plans will be prepared at once for the erection of a factory for London Motors, Ltd., East London, Ont. W. Stansell, manager.

The Anglin-Norcross, Ltd., 65 Victoria St., Montreal, have received the general contract for an addition to the power house to cost $80,000 for the Montreal Light, Heat and Power Co., 83 Craig St., Montreal, at Cedar, Que.

The iron foundry owned by Fleming Brothers, Cabot St., Halifax, N.S., which was destroyed by fire with loss of $15,000 will be rebuilt.

It has been announced by C. L. Thompson, of the Martin Engineering Co., Niagara Falls, Ont., that plans have been prepared for a brick, tile and glazed tile plant at Winnipeg, the capacity of which it is stated will be 20,000,000 brick annually.

A rotary brick press is being placed on the market by the Rotary Brick Machine Company, of Canada, Limited, 117 University Ave., Toronto, for which they claim a capacity of 56,000 per day.

Ferguson Manufacturing Co., Ltd., has been incorporated with a capital of $40,000 and head office at London, Ontario, to carry on the business of brass and iron founders, etc.

The Auto Rim Co., Ltd., has been incorporated with a capital of $250,000 and head office at Toronto, to manufacture and deal in engines, machinery and tools of all kinds.

Walker Twist Drill and Tool Co., Ltd., has been granted incorporation with a capital of $750,000 and head office at Walkerville, to manufacture drills, cutters, reamers, screws, bolts, nuts, etc.

The St. Maurice Power Co., Ltd., Montreal, has been incorporated with a capital of $8,000,000, to carry on the business of an electric light, heat and power company, to build power station, etc.

During the discussion following the report of the postal and parliamentary committee at the June 10th session of the Canadian Weekly Newspaper Association, A. W. Dunlop, Neepawa, Man., urged that the government be asked to abolish free postal delivery for newspapers. The report was adopted.

W. J. Keyes, instructor of printing classes in Kelvy Technical school, Winnipeg, addressed the Saskatchewan Press Association in the University at Saskatoon on June 3rd, on the subject of "Advertising in a Country Weekly." Description and uses of the various kinds of type was one of Mr. Keyes' main points. He also showed the correct and incorrect ways of constructing display advertisements, recommended the use of single rulings to outline ads. An address was also given by David Miller, secretary treasurer of the Western Press, Moose Jaw, on "System in the Front Office." Mr. Miller dealt mainly with the use of the synoptic in the bookkeeping system. The third speaker of the morning session was Walter P. Confarr.

The Edmonton Journal has announced the appointment of John M. Imrie, as managing director of that newspaper in succession to the late M. R. Jennings, also the election to its board of directors of Charles R. Morrison and Arthur Yockney, who have been on the staff for many years as managing editor and business manager, respectively. Mr. Imrie has had a wide experience in newspaper work. He was manager of the Canadian Press Association, and later of the Canadian Daily Newspaper Association. Recently he has been a member of the head office staff of William Southam and Sons, Ltd., where he was doing special work of an executive character for various papers in which that company is interested. His appointment takes effect on July 1st.

Reeve E. A. Harris, editor of the Burlington Gazette, left last week with Mrs. Harris, on the Press excursion to Vancouver, B.C.

## $6 PER DAY TO BE MINIMUM WAGE

**No Sunday Work Will be Done on This New Ford Acquisition.**

Beginning July 1st, each employee of the Detroit Ironton Railroad will receive six dollars a day minimum wage. This is the same rate being paid to workers at the various Ford automobile plants. Evidently Henry intends to play no favorites. In addition, bonuses for efficiency will be allowed.

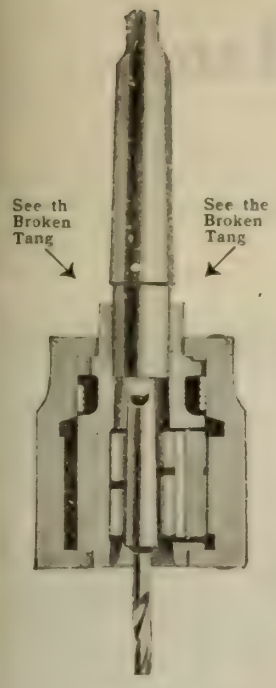
Eight hours will constitute a day's work, and there will be no turn anywhere on the system from 6 p.m. Saturday until 6 a.m. Monday.

There are 1,327 employees on the road, which runs from Detroit to Ironton, Ohio. A total of 467 miles of trackage is operated. The road taps the rich Ohio coal fields and connects with the Baltimore and Ohio and th Lake Shore and Michigan Souther Railroads.

## BRANTFORD PLANTS ARE IN GOOD SHAPI

**Several Plants Increasing Staff, Whil Many Others are Normal or Even Slightly Above the Normal Point.**

According to the industrial census Brantford, Ont., things are going fih Of the 48 largest industrial plants, onl two have less than 50 per cent. of the employees at work, save those whi are totally closed. Four of the factori are employing more than normal, th Cockshutt Plow Company is employin approximately 110 per cent. of its nun ber of normal employees. The Bran ford Roofing company a few days ag commenced the use of a night staff an by so doing increased the number employees on its payroll to 40 per cen above normal. The Brant Creamer one of the smaller industries of the cit is employing about 80 per cent. mo than under normal conditions, and th A. J. Reach Company has slightly ov five per cent, more employees tha usual.



Fifteen factories are employing the full regular staff. Such large concer as the Verity Plow Company, Watso Manufacturing, Brantford Corda Company, American Radiator Compan are included in this list and the fa that they have such a high percenta of their employees at work at the pre ent time has meant considerable t wards the solving of the unemployme situation in that city.

In addition to those large concer the following somewhat smaller indu tries report that 100 per cent. of the regular employees are at work at t present time: Brantford Coffee a Spice Co., Brantford Felt Novelty C Brantford Oven and Rack Co., Bra ford Willow Works, J. and J. Cash C Cummings Button Co., Dominion Dre Co., Dominion Flour Mills, S. C. Joh son and Sons, Scarfe and Co. The factories constitute some of the large of the smaller factories and their 1 per cent. record represents the emplo ment of a large number of men.
2-column head

### MACHINE TOOLS.

Wm. Sellers & Co., Inc., Philadelph Pa., have issued their catalogue G-2 This book contains a description their line of machine tools for railw and machine shop equipment, this i cluding bending machines, boring m chines, boring and turning mills, rad drills, grinding machines, steam ha mers, lathes, planing machines, slotti machines, etc., etc.

# Aikenhead's

*Grips the Entire Shank— Never Slips*

## Wahlstrom Chucks

The clutch of the Wahlstrom positively cannot slip. Its instant-acting jaws close on the entire shank with a grip that becomes firmer and firmer as the resistance to the tool increases.

There's no time lost in waste motion with the Wahlstrom Chuck. It is automatic and instantaneous in action. Two seconds is all you need to change from drilling to reaming, counterboring or tapping—and you don't stop the spindle.

In addition to regular drill press work they will increase production of lathes for burring, turning, filing, etc.

Made in two different styles. One style holds No. 1, 2, or 3 Morse Taper Shank Drills —with or without a tang. The other style is made in three sizes, which hold all sizes of straight shank tools from 1-4 to 1-inch.

*The World's Standard of Accurate Gauging*

## Johansson

The "Limit System" introduced by a set of Johansson Gauges to your shop will assure equal results on all work, even in the hands of unskilled operators.

Johansson Gauges are the fulfillment of an ideal in measuring tools heretofore unattainable. They combine the advantages of both line and end measures. Like line measures they give all sizes within their range—like end measures they are convenient, solid, non-adjustable blocks of steel. They insure the same result any number of times and in the hands of any number of mechanics. This fact has made them indispensable where the work of one shop is to be assembled with the work of others.

No individual to-day is independent of the machine-shop. No machine-shop to-day can afford to be independent of Johansson gauges. They save time, decrease costs and increase both the quantity and quality of the work, factors of vital importance in these days of keen competition.

# From a $500 Bush League Pitcher to a $5000 Business Man

## How One Man Took Advantage of an Opportunity to Build Up a Successful Business on a "Shoe String"

Where successful efforts were awarded with cheers and applause from the crowd—and a $500 yearly salary.

As our old friend Aesop would say, "Once upon a time"—But Andy Van Dusen, as we will call him, was no fabulous character. He was the star pitcher on the Blank Base Ball Team the year they topped the list in their League.

After the "last call" Andy wrapped up his uniform in moth balls and hit for a winter's berth. He landed in a plant at the North end of the city where they manufactured Grinding Machines that are used in automobile factories for grinding cylinder bores, piston rings, gears and similar parts.

The former star ball player soon became quite an expert in setting up and running these machines. So when one day a customer who had bought two or three, sent in a request for some one to show his operators how to keep things going on high, Andy was sent to stage the show.

It was while he was on this job that he saw how easy a dandy business could be built up on only a trifling capital, provided the man had sand, some mechanical knowledge and was willing to work like a "bee in a tar barrel."

That night he "built a few castles." He saw himself, with a shop mate, running a business of their own. They had equipped a plant for regrinding the bores of auto and truck cylinders. He visioned mountains of cylinder blocks piled around his doorway and saw the results of his three-shift efforts being trucked away by satisfied customers, who were saved days and weeks of time by not having to send them back to the manufacturers.

Andy's "air castles" were built on a firm foundation because he knew, as do most auto owners and repair men, that a reground cylinder fitted with new oversize pistons and snug rings makes a far better running motor than one fresh from factory where they do not finish their cylinders by grinding.

He had learned that castings in a new engine were "green" and unseasoned; that when they are put to work the heat from the explosions more or less distorts the cylinder bore and permits leakage and power loss.

Andy was also aware that over 8,000,000 automobiles, trucks, tractors and motorcycles were now operating in this country. Sooner or later each individual one of these would require overhauling and grinding. *He determined to get his share of this business.*

The next morning Andy told his boss that he was going to quit and go into business for himself, if he would sell him one of the cylinder grinding machines he had learned so well to run and give him a little time to pay for it. He got the machine.

Andy and his partner rented a room in a down town section. They set up their Cylinder Grinder—a Heald, of course—and backed it up with a lathe, a vise and a few bench tools.

Here, a like amount of effort applied to business amounts in a $5000 annual income.

He notified the garage men and truck fleet owners that he was "all set" and from then on there has never been a time that cylinders have not littered the floor, waiting their turn to be reground and refitted.

Andy's advertising bills were small, every customer was a booster. The first Grinder was soon paid for and before the next season's work loomed up, Heald No. 2 was added to the family and put to work earning bright dollars for the boys who had the courage to dig in and go to it, even if they didn't have a fat roll in their pocket to start on.

If you are desirous of learning Andy's faith in the future of his business, just try to sign him up in any of the big leagues now.

Andy's case is not exceptional We could name scores.

Just a few days ago the writer was in a shop in one of the largest cities in this country where the business has been literally built up on Heald Cylinder Grinders, the first machine having been put in March, 1918, and the man who took me there said that when the owner started he didn't have over $300.00 to his name but now his investment is easily worth $300,000. So you see what can be done starting on a "shoe string" as they say, IF YOU HAVE THE RIGHT STRING TO START WITH.

There is just one machine for this work which is made right, has the needed capacity, is durable and can do rapid and efficient work that will satisfy both the owner and the customer it serves, and that is the one made by Andy's old boss—The Heald Machine Company of Worcester, Mass.

These people have been building grinding machines for fifteen years for the big auto factories where quantity and quality production must be the greatest possible, and in every one of the shops building the better grade of cars, these machines will be found in daily operation.

They build rotary machines for grinding the edges of piston rings, to make them the right thickness to fit in the piston; and internal grinding machines to finish the gears, the ball bearings, and all the holes in the many hardened sleeves and bushings used in the wonderful machines that carry us and our friends from place to place—to work or to play—in Summer or in Winter—in sunshine or in rain—by day or by night—whatever our need may be.

The Heald Machine Company has the facilities, the experience, the right machines and the desire to help you to make a success of handling this line of work, and we shall be pleased to have you call upon us at our factory or any of our branches or agencies, either in person or by telephone or by wire or wireless, and the same will receive our best attention.

# THINKS EFFECT ON CANADIAN MANUFACTURERS WILL BE EXCELLENT

An important change, with considerable effect on American imports into Canada, in computing the value for duty of currencies of invoices from countries where the rate of exchange is adverse to Canada, has been put into force by the Department of Inland Revenue and Customs, and came into effect on June 6th.

On an invoice of goods imported from the States, it is suggested in an example given in the memorandum issued by the Department to local customs collectors, where actual home consumption value is $100, and the premium of exchange is 12 per cent., the value for duty purposes will be $112. Where there is heavily depreciated currency, on the other hand, not more than 50 per cent. depreciation of the proclaimed value of the currency is to be allowed by customs for computing values of invoices for duty. Thus the German mark, whose proclaimed value is 23.82 cents, will be taken as worth 11.91 cents, though actually worth much below that figure.

"These changes will help Canadian and British manufacturers and merchants considerably," stated Captain E. J. Edwards, Senior British Trade Commissioner, yesterday, "as well as other Empire merchants who export to Canada, by giving them an additional preference, but on a perfectly fair basis. I understand that importers are upset at the change, but it is after all on the same basis as that in use by American customs on Canadian imports into that country. They levy duty on Canadian invoices in American currency, which gives added protection to their manufacturers, a reasonable proceeding for any country where, as in Canada, protection is needed to maintain home industries.

**An Excellent Effect.**

"I think the effect on British importers and Canadian manufacturers will be excellent," continued Capt. Edwards, "as added protection amounting to 3 or 4 per cent. will be given, and I hope that this plan, outlined by Sir Henry Drayton, Minister of Finance, in his recent budget speech, will soon evidence the effect for which he designed it, the expansion of Canadian industry and the purchase of supplies within the Empire as far as possible. It will be recalled that the Minister intimated that bankruptcy lay ahead of Canada if she continued to buy at her present alarming rate from the United States Anything that will assist, as this must, in the development of British trade, naturally has my hearty approval, and I look forward to a consequent early improvement in British trade here. There are admittedly some lines in which Great Britain has not yet recovered her pre-war ability to manufacture at low prices, and this will give her manufacturers useful assistance.

"As to the provision that customs shall not allow any reduction more than 50 per cent. of standard currencies in computing values, the recent inrush of German manufacturers into Canada, with a consequent bad effect on British imports, and as Canadian manufacturers tell us, on their factories, in my judgment proves that in this respect too we shall also both benefit, though, as German imports are still comparatively insignificant, not to such an extent as provided by the new regulations on goods from the States and other countries, whose exchange rate is adverse to Canada."

## PERSONAL.

R. B. Morley, who has been general manager and secretary-treasurer of the Ontario Safety League for seven years, has been appointed secretary-treasurer of the Industrial Accident Prevention Association, an organization founded under the authority of the Workmen's Compensation Act. Although he has resigned his position with the league, he still holds the position of honorary secretary. J. F. H. Wyse, who has been organizer and engineer of the league since its inception, takes over Mr. Morley's former position.

Mr. Oskar Kylin has recently been appointed general sales manager of the Foster Machine Co., Elkhart, Ind. For the past five years Mr. Kylin has been chief engineer, and a member of the executive board. Although taking on this new position, he still retains his former duties as well.

The Mechanical Leathers, Ltd., who are the Canadian representatives of the Chicago Rawhide Mfg. Co., have supplied us with some interesting information regarding the three directors of their company.

The president, Richard W. Coleman, has charge of the engineering and sales depts., and previous to his present position was belt and sales engineer for the Chicago Rawhide Co., coming to Canada as their representative in 1913. Since May 1st he has been occupying his new position.

The secretary-treasurer, Herbert R. Allay, was born in Toronto, and is a B.A. of the University of Toronto. He has had varied experiences in the past war, rising from Lieutenant in the Q.O.R., up to Major. His industrial activities have included various concerns, including the Goodyear Tire & Rubber Co., which concern he left to form the present company.

E. W. Wright, partner in the Toronto firm of Rowell, Reid, Wood, Wright & McMillan, Solicitors, is the third Director. Mr. Wright also served in the past war, and is well known in legal and business circles throughout Canada.

This concern handles the following lines:—High speed, heavy duty, moisture proof, heat proof, friction proof and oil proof belting, rawhide gears blanks, frictions, lacings, hammers mallets and mauls, also "Krome" cups gaskets, washers, discs, and hydraulic packing. Their line also includes motor car and commercial leathers, shoe findings, etc.

## IMPORTANT NOTE.

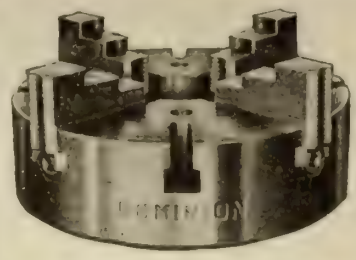
The article on welding in this issue was procured through the courtesy of the Electric Arc Cutting and Welding Co., Newark, N.J., Mr. Holslag being chief engineer of that company.

## AUTOMATIC COUNTERS.

"Census Takers of Industry" is the title of the catalogue No. 31 issued by the Root Co., Bristol, Conn. Various photographs are shown of their counters also typical installations.

### WIRELESS TELEPHONY

The first illustration of wireless telephony for commercial purposes in the United Kingdom was put to work recently at Liverpool between the head offices of the Mersey Docks and Harbor Board and the Mersey bar lightship, 12 miles away. The other two lightships guarding the Mersey entrance are connected with the shore by telegraph cables, but that is impracticable in the case of the bar lightship owing to the heavy currents. A portable Marconi set of 100-watt power with a 35 miles' range is employed and the wave length adopted is 400 m., to minimize the possibility of interference with other wireless stations.



### IRONSTONE DEPOSIT

A fresh deposit of ironstone has been discovered in Great Britain after boring operations to a depth of nearly 500 feet. The seam is close on thirty feet thick and is expected to prove of great commercial value. A larger bore will now be sunk, and the result of the further investigation is awaited with keen interest.

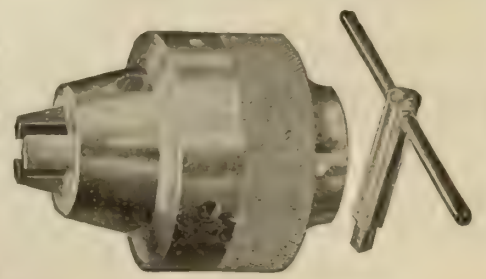
SKINNER DRILL CHUCKS
GIVE BETTER SERVICE

TRADE MARK

Skinner Drill Chucks eliminate most of the trouble of accurate drilling operations, simply because they are built right to hold the drill or tap accurately and truly in center. The hardened jaws are ground true.



They are easy to handle, too, as there are no exposed gears to pinch the fingers.

The long life of Skinner Drill Chucks is due to the great care we exercise they are built. Made of the best materials available for the purpose. All working parts hardened to resist wear, and of sufficient strength to rigidly hold the tool to the work.

These Drill Chucks are all described in our catalogue, which will be sent to you with prices upon request.

# CUTTING COSTS *with* JOHANSSON SNAP GAGES

*It is easy to set Johansson Snap Gages to the desired limits with great accuracy. You can also depend on their maintaining their accuracy.*

WHY take it all out of the pay envelope? In reducing your costs during this period of reconstruction, let the LIMIT SYSTEM do its share. Cut down the scrap pile and thus cut your production costs by using the LIMIT SYSTEM with Johansson Adjustable Limit Snap Gages set to the acknowledged standard of Johansson accuracy.

THE LIMIT SYSTEM, or in other words, the making of interchangeable parts *within limits*, demands dependable gages if it is to be used with the greatest efficiency. Johansson Adjustable Limit Snap Gages are ideal for the operation of the LIMIT SYSTEM. Note these features of their construction.

FRAME of Swedish Gray Iron—cannot be distorted. Tool Steel Gaging Plugs with extra large *flat* contact faces which do not turn in the frame, having end movement only. Clamping screws force the gaging plugs to seat firmly against the adjusting screws. Adjusting screws can be readily sealed to prevent tampering. Temperature changes prevented by means of the Johansson Insulated Grip.

Johansson ACCURACY

EACH of the following Machine Tool Headquarters carries a large assortment of the regular sizes of Johansson Limit Snap Gages. In conjunction with Johansson factory representatives, they are at all times ready to give you complete gage service.

# *Oakite Saves Over $4,000 a Year On One Cleaning Operation*

This Advertisement is one of a series based on actual occurrences in the

In a certain plant, small brass parts were washed with soda ash to remove rubber compound. Soda ash left a sediment, so 5 girls had to be employed to scrub the parts with soap to remove the sediment.

This operation was slow, tedious and costly.

An Oakite representative was given an opportunity to investigate cleaning conditions in this plant. The use of 30 lbs. of Oakite every week to replace 444 lbs. of soda ash was recommended and Oakite was adopted.

The parts now come from the tank absolutely clean. No sediment. No scrubbing.

Oakite has saved this plant $83.52 weekly on one cleaning operation—or more than $4,000 a year.

We have a representative in your territory. May we ask him to call at your plant and have him go over your cleaning requirements with you? This will take but a few minutes of your time, and you can find out just what it would involve to run a competitive test on your work. He can perhaps indicate just what results you can expect and offer suggestions as to methods and materials best suited to your work.

Now is the time to cut expenses. A request from you for an Oakite service man to call to look over your cleaning problem places you under no expense or obligation whatever. Write to-day.

*Resident Canadian Representatives: Mr. C. P. Murphy, Toronto, and Mr. C. Burgin, Montreal*

**OAKITE** MANUFACTURED BY OAKLEY CHEMICAL CO. 44 THAMES STREET NEW YORK

## DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

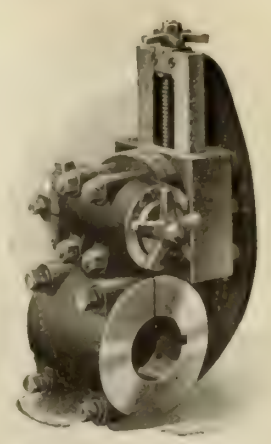
# Widen The Scope of Machining Operations



THE Horizontal Boring, Milling and Drilling Machine with its various attachments, is a highly important factor in any plant.

In machining parts requiring a series of boring, milling, reaming and drilling operations, the Landis is noted as a time saver, because these varied machinings can be accomplished with a single set-up of work.

With the addition of a universal table, facing heads or other accessories best suited to your work, this boring machine has unlimited possibilities, and at all times can be relied upon to handle the most difficult jobs, accurately and quickly.

*Our catalogue tells more about this powerful tool. Write for it.*

# The New Canadian-Detroit Double-D Rolled Drill

*Made in Canada*

PRODUCTION requirements in an ever-increasing number of plants necessitate the use of a strong, accurate drill, specially designed for hard drop forgings, steel castings, and other alloy steels equally tough and difficult to drill.

For this service we have developed a hot rolled process drill known as the Canadian-Detroit Double-D (DD) Rolled Drill. It combines the strength of the forged type drill with the accuracy and uniformity of the milled type.

The flute of the DD is formed straight from the bar stock by successive passes through specially built and patented rolls at a temperature of 1850° F. This mechanical rolling of the flutes produces a refinement and uniformity in the grain of the steel and gives additional density at the centre and at the outer edge. Each drill is rolled separately, and the rolls are so designed and operated as to produce the same uniform increase in web thickness as is obtained in high-grade drill of the milled type.

The fluted drill is reheated and twisted in a specially designed automatic machine. The twisting process is held absolutely uniform, giving the same increase in helix angle from shank to point, 27° to 32°. This standard has been adopted on our milled drills and has been proven by exhaustive experiments to be the most efficient.

The DD has increased production and cut drilling costs in many of the finest plants in Canada. A fair test will convince you.

Manufactured and carried in stock at Walkerville in all sizes from $\frac{1}{2}$ inch to $1\frac{1}{2}$ inches.

We also manufacture and carry in stock all sizes and types of high speed and carbon milled drills.

# Cab Tire Cable

## The Cable De Luxe for Industrial Purposes

This advertisement illustrates:

**A length of Northern Electric Cab Tire Cable**
**One Northern Electric No. 511 Marine Plug and Receptacle**
**One Northern Electric No. 300 Hand Portable**

This combination is ideal for Industrial Portables. It is especially adapted for use in damp localities, or where gas or oil fumes abound, and where other types of cable would be subject to mechanical injury.

Because of its flexibility and durability, Cab Tire Cable is in a class by itself for industrial purposes, and the ever-increasing orders received from Machine Shops and Industrial Plants all over Canada prove its merit and popularity.

Our nearest house will give your inquiries immediate attention.

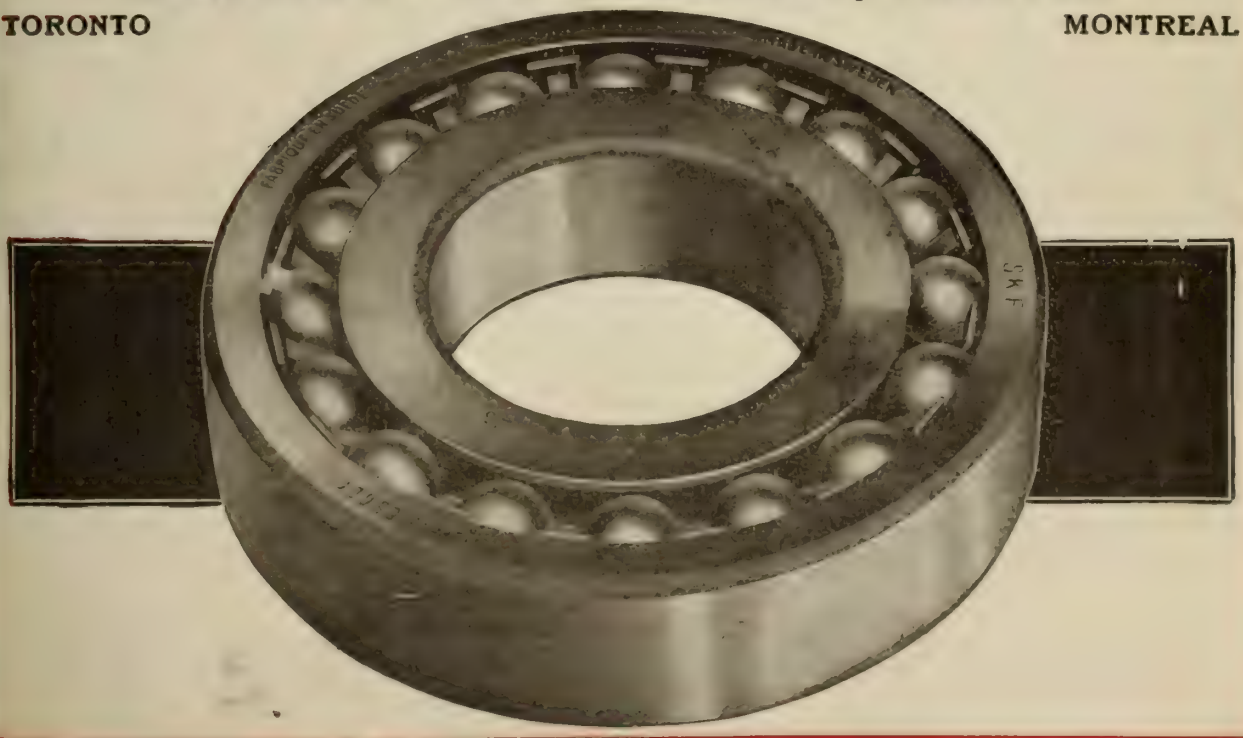
## THOUSANDS ARE LOST

**In Oiling and Re-babbiting Bearings, and Overhauling Transmissions**

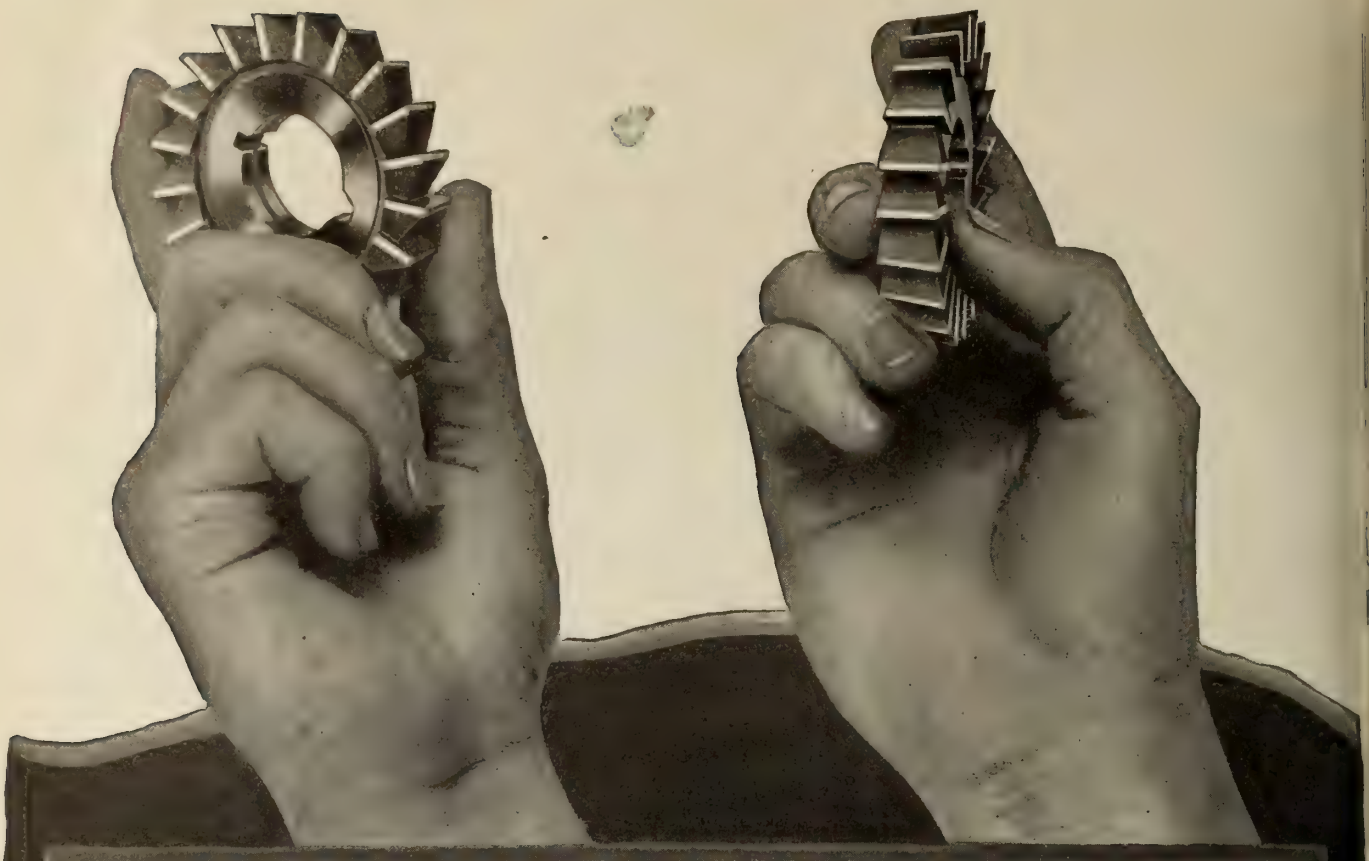
For the same reasons—inefficient bearings—thousand more are lost

—in slow speed and low production

—in imperfect and poorly finished products



—in variations in products making finishing by hand necessary.



**SKF** engineers will show you how they have helped manufacturers throughout the world to avoid these losses. They bring to you without charge experience gained in industrial plants of every kind. They offer you in addition, the services of the **SKF** Industrial Laboratory—to solve any new problem that may arise in your plant.

Consult **SKF** engineers without incurring either expense or obligation.

## CANADIAN SKF COMPANY, LIMITED

# THE JOHNSON FRICTION CLUTCH

## The Case Against the Countershaft

The old familiar countershaft drive, through cross belts and tight and loose pulleys, stands accused of the following offences against efficiency:

1. Involves needless equipment.
2. Costs too much to set up.
3. Prevents economical and systematic use of space.
4. Operates sluggishly.
5. Multiplies belt troubles and the resultant cost of upkeep.

Modern practice has discarded the antiquated countershaft for the simplicity and efficiency of the clutch drive direct from lineshaft.

### Adopt the Johnson Lineshaft Drive

The economical, efficient and durable method of power transmission through friction control.

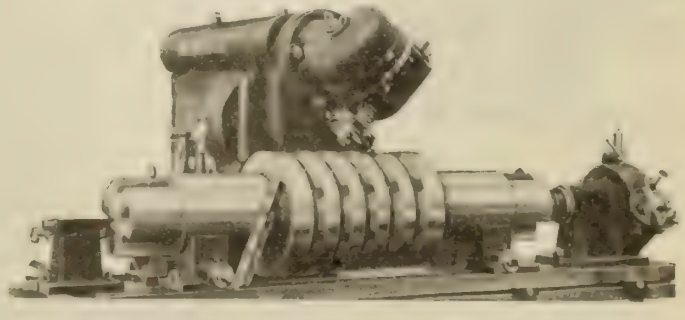
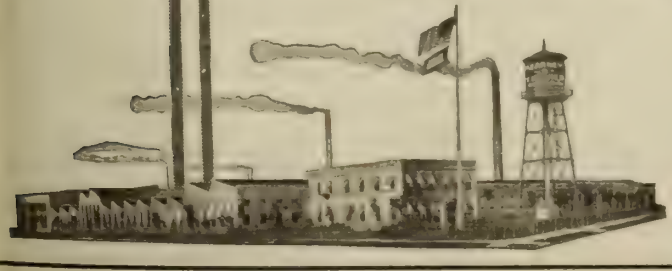
# MILWAUKEE MILLING MACHINES



## Efficient on Light and Heavy Milling



Heavy milling jobs are not unknown to Milwaukee Universal Milling Machines, while delicate and intricate ones are efficiently performed with little effort.

Both light and heavy milling operations are handled with such smoothness and accuracy that the finest results are obtained. Because Milwaukee Universal Milling Machines perform such a wide variety of work, they are particularly well adapted for the tool-room.

The jobs shown in the two illustrations are representative of "Milwaukee" adaptability. The upper illustration shows a jig being bored with a fly cutter. The lower illustrates the milling of a chilled roll with the use of a Universal Milling Attachment.

# ROYLITE
## CLEANER

## *Roylite Giving Good Results in a Hamilton Plant*

In above illustration (drawn from actual photograph) is seen the cleaning of Die Castings with *Roylite Cleaner* This operation is performed before the castings are plated. and was difficult because the heavy oil and grease on work could not be cleaned effectively without discoloring the soft metal. *Roylite* proved very successful and removed every particle of grease and dirt without injuring the metal. It is doing it quicker and more economically than any other solution has ever done it before. The head plater here says *Roylite* is the best solution he has ever had.

In this case the castings are immersed for three seconds in *Roylite Cleaner*. Only four ounces of *Roylite* are required to the gallon and very little extra cleaner is required to keep the solution up to required strength.

*Roylite* works equally satisfactorily on Brass, Steel, Copper or any other metal.

**Roylite Cleaner lasts longer, works quicker and costs less—prove it to your own satisfaction with a trial order. Sample sent on approval. Our experts give free demonstration.**

# Drilling Two Different Parts on One Machine

## Multiple Drilling. Its Uses and Advantages—Drilling Steam Cylinders—Transmission Cases—Drive Axle Arms—Crank Cases—Cylinder Blocks—Washing Machine Parts and Steel Drive Gears.

By J. H. MOORE

TO ENTER the subject of "Multiple Spindle Drilling" properly, one must first look back quite a few years, picturing in their mind the type of single spindle drill that was then existent. Not only was the design very crude and the feeds and speeds of very uncertain character, but the chief drawback was that only one hole could be drilled at a time. True, there are various jobs where a single spindle drill is quite sufficient, but in many cases multiple spindles are absolutely essential if economical production is to be secured.

The automotive industry for example would never have made such rapid strides in production had it not been for multiple spindle drills, or in some cases, multiple spindle heads mounted on single spindle machines. One of the necessities of today in any industrial plant is the conservation of time. Labor is expensive, therefore if production costs are to be kept low, each worker's time must be made the most of. As it is impossible to get more than a certain amount of energy out of any man, his efforts must be supplemented by mechanical means, therefore in the case of drilling, designers decided to make machines that would drill more than one hole at a time. As years rolled on, the designs improved, until at present a book could be written on the various types existent. In many cases the machine is now built to suit the part, especially where the quantity to be produced warrants such procedure.

Like any other time-saving machine tool, the multiple spindle drill cannot do its best work unless equipped with accurate and rapid working fixtures. True, even without the fixtures, the production will be greater than with the single spindle, but to get the most out of the machine, the question of jig and fixture design should receive close attention. The examples to follow are installations that are in actual operation in various plants throughout the country and bear out the previous statement regarding the advisability of using modern fixtures.

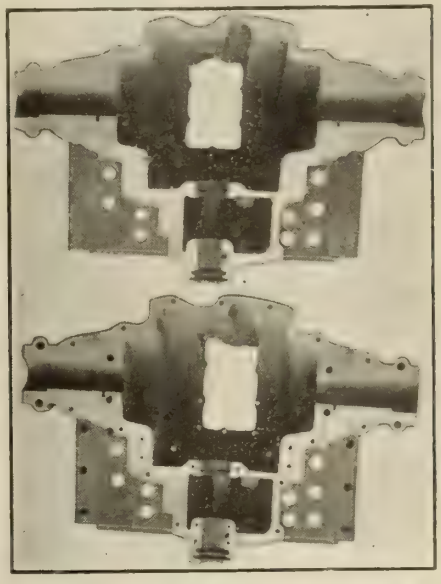

FIG. 3—TRANSMISSION CASE SHOWING PART BEFORE AND AFTER DRILLING.

Illustrations through the courtesy of National Automatic Tool Co., Richmond, Ind

### Examples of Work

Fig. 1 illustrates a steam cylinder and yoke or a duplex steam pump. Note

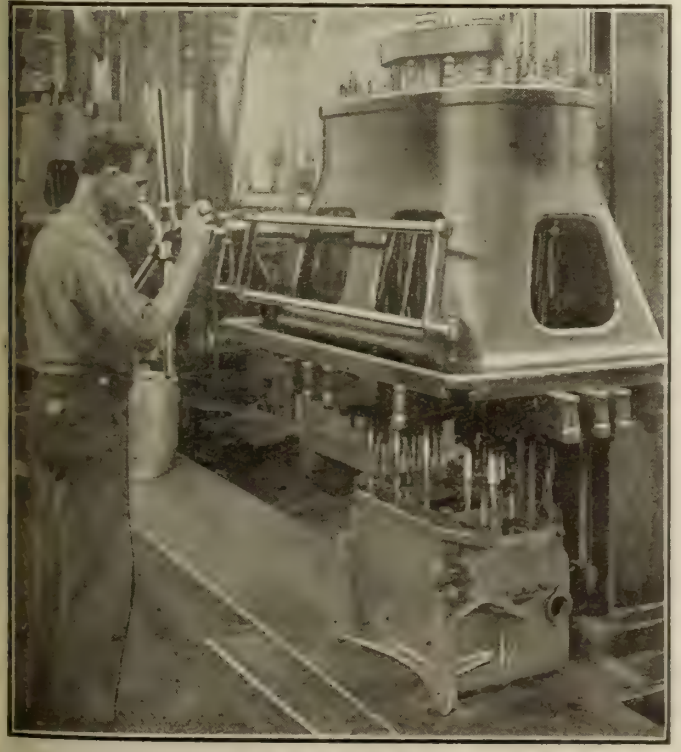

FIG. 1—DRILLING A STEAM CYLINDER FOR DUPLEX STEAM PUMP.

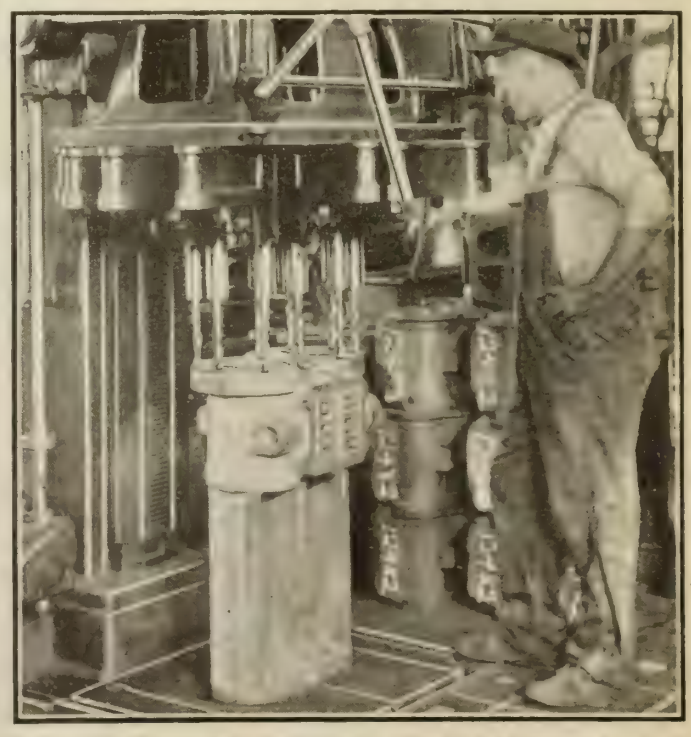

FIG. 7—MACHINES DRILLING THE CYLINDERS AND CRANK CASES.

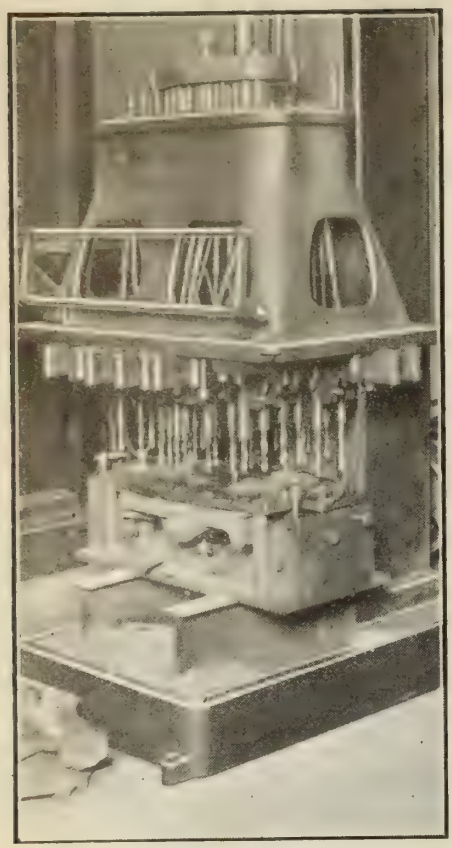

FIG. 4—TRANSMISSION CASE BEING DRILLED.

that twelve drills are in use on this machine. This operation, which is accomplished in the plant of Vogt Bros. Mfg. Co., Louisville, Ky., consists of drilling 30 ¾-in. holes to a depth of 1½ inches. Twelve holes are drilled at one setting and the present production is 20 per hour, while the former method produced only ⅓ of this amount.

It would be a good plan to mention at this point that the type of machine depicted has a patented method of drill speed changing, the speed of every spindle being independent of the speed of any other spindle. This allows the operator to change at will to the correct speed required for the size or type of tool being used. Any spindle not being used is thrown into neutral, thus saving both wear and power.

The benefit of this speed changing feature is self-apparent, for, when drilling, reaming, spot facing, etc., simultaneously, each tool can run at its correct working speed. Notched plungers on the top of head indicate the speed at which the tool is working.

Before leaving the question of feeds and speeds, it might be mentioned that this type of machine, equipped with the independent change, has six drill speeds, which may be used either as six single speeds or as three double speeds, the ratio of the low to the high being approximately 1 to 2. There are six rates of power feed, this permitting a range from .73 in. to 4.74 in. per minute. As it is not the design we are after so much as examples of work performed we will proceed to Fig. 3 which shows a transmission case having 41 holes, and which is drilled in seven minutes.

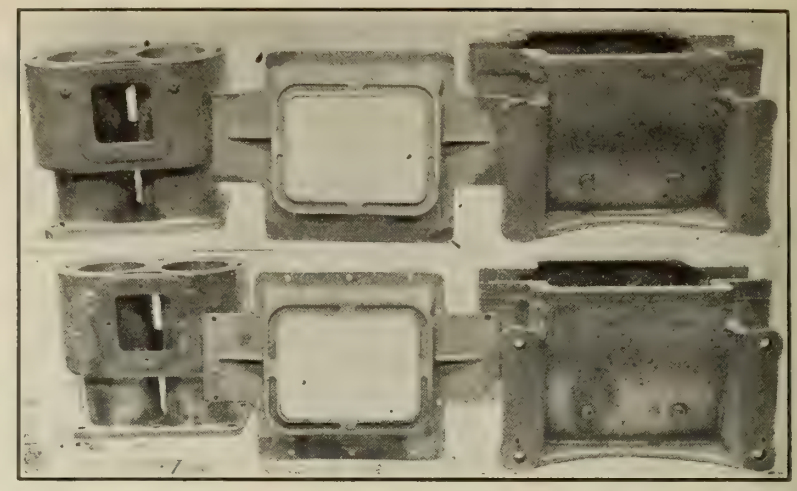

FIG. 6—CYLINDERS AND CRANK CASES BEFORE AND AFTER DRILLING.

Fig. 4 depicts the drilling machine in operation, and the photograph was taken in the plant of the Cleveland Tractor Co., Cleveland, Ohio. The part is used on the Cletrac tractor and is the lower half of the transmission case. The depth of holes ranges from 7-16 in. to 1⅝ in., and the diameter of the drills also vary. The floor to floor time, as previously stated, is only seven minutes. Note the jig used, as this is one of the production assets.

Fig. 5 shows clearly the benefits of proper fixtures. In this case two different parts are drilled on the one machine, and both are completed at one time. This is made possible by the independent speed feature already mentioned, also by the use of two tumbling jigs. One piece is a drive axle arm in which nineteen holes are drilled, while the other part is an upper pivot bracket in which eight holes are drilled. The jigs run on special carriages, mounted on a rail as shown, this making it easy for the operator to get the work from a loading position to an unloading position and vice versa.

The above operation is performed in the Moline Plow Co., and on the two jobs they obtain a production of fifteen an hour on the drive axle arms, and eight an hour on the upper pivot brackets.

At the Hart-Parr Co., Charles City, Iowa, they drill practically all their cylinders and crank cases on similar machines, to that shown in Fig 7. In this case the parts are shown at Fig. 6, and 59 holes of different sizes are drilled in three settings, from 16 to 26 holes being drilled at one setting. The production is 50 per day, as compared to 7 per day before they used the present method of drilling.

It will be noted in this photograph that the drills form a complete chain, insomuch that they are connected by means of a long steel plate on which the parts are slid. This is splendid practice, and should be followed out, except where impossible, or where gravity conveyors are in handy position.

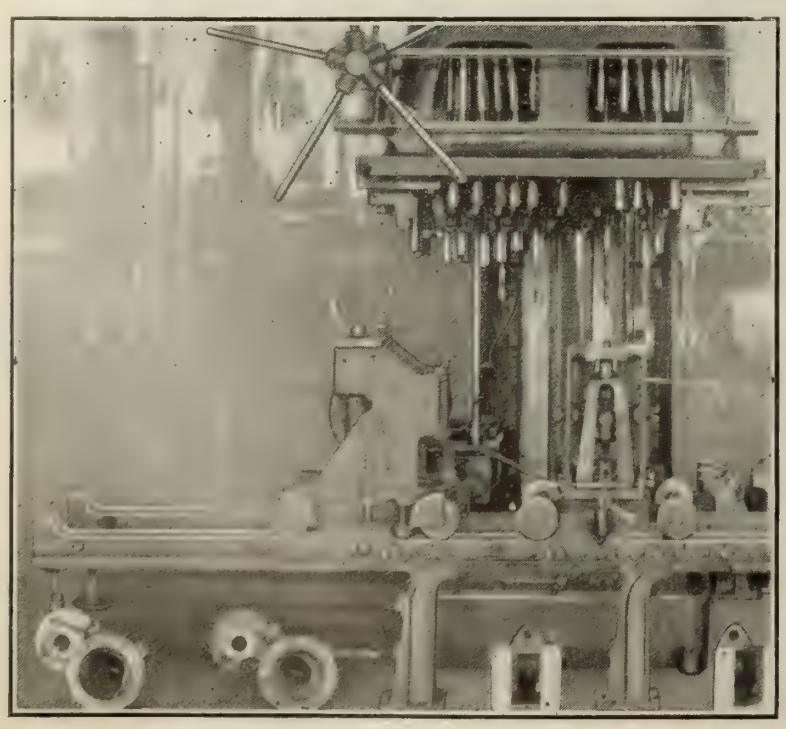

FIG. 5—TWO DIFFERENT PARTS DRILLED ON THE SAME MACHINE.

### Drilling Cylinder Blocks

At the plant of H. I. Walker Co., they drill their grey iron cylinder blocks as shown at Fig. 8, using a turnover jig for holding and locating the pieces. 36 stud holes are drilled to a depth of ⅝ in., and 7 blocks are completed per hour. In this case the jig is again mounted on

ils, and moved along the production ne.

To describe and illustrate all the perations possible on these machines ould take a volume in itself, but for a w other examples we will consider ord pictures only. At the plant of the Willys-Overland, Ltd., Toronto, Canada, ney use two such machines as shown in ig. 8, in parallel. The machines are onnected up by rail, and a turnover jig f rather heavier design to that in Fig. is used. The part produced is the ylinder block for the Overland car, and ne machine is equipped for drilling, hile the other is fitted up for tapping. he block never leaves the jig until completed, for after the part is drilled, it is erely moved along the rails until it is nder the machine doing the tapping. 8 holes are completed at the one operaion, there being 14 holes on one side, nd 24 on the other. The jig itself is evolved 180 degrees by means of a andwheel, a worm, and worm wheel, a pecial indexing attachment being used.

The Moline Plow Co. drill their brill ears at the rate of 20 per hour, the holes eing as follows: Eighteen 17-64 in.— ⅛ in. deep, and eight 33-64 in.—1⅛ in. leep.

Another plant drills 10 holes in nickle teel drive gears ½ in. thick at the rate of 125 gears per hour. Special jigs are used, as is also the case in the previous example cited.

Another concern drill washing machine parts by the multiple spindle process, and the aluminum base for their engine has three holes in it which are drilled on what is known as a No. 12 machine. Formerly this base was drilled one hole at a time, and a production of 40 per hour was the best they could get. This is now increased to 80 bases per hour.

In another plant 5,544—⅝ in holes are being drilled every day on one machine in 1½ cedar. The parts drilled are for rotary drying machines and the pieces are made of 1½ in thick cedar. The boards are 6 ft. long by 1 ft. 9 in. wide, and 396 holes are drilled in each piece. 14 boards are completed every day.

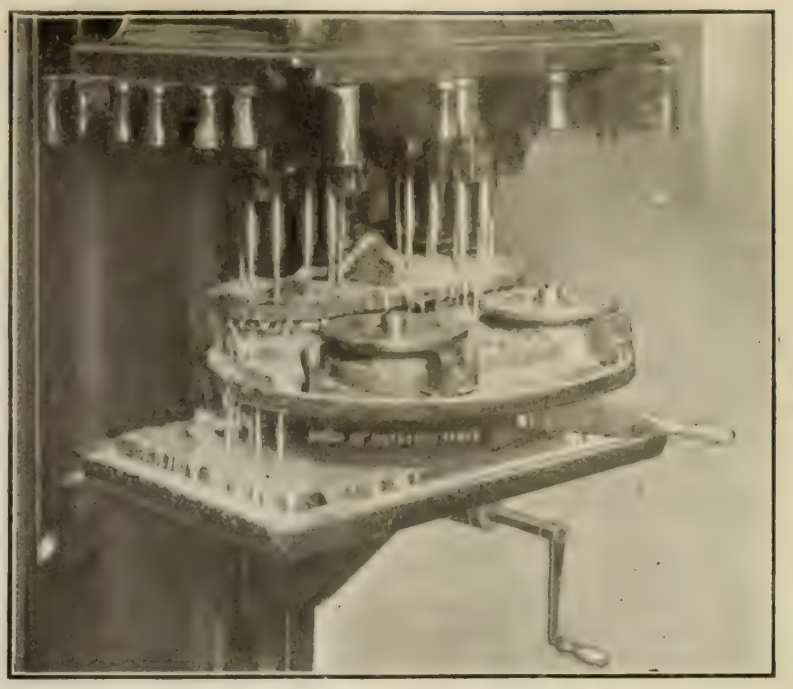

FIG. 9—DRILLING STEEL DRIVE GEARS.

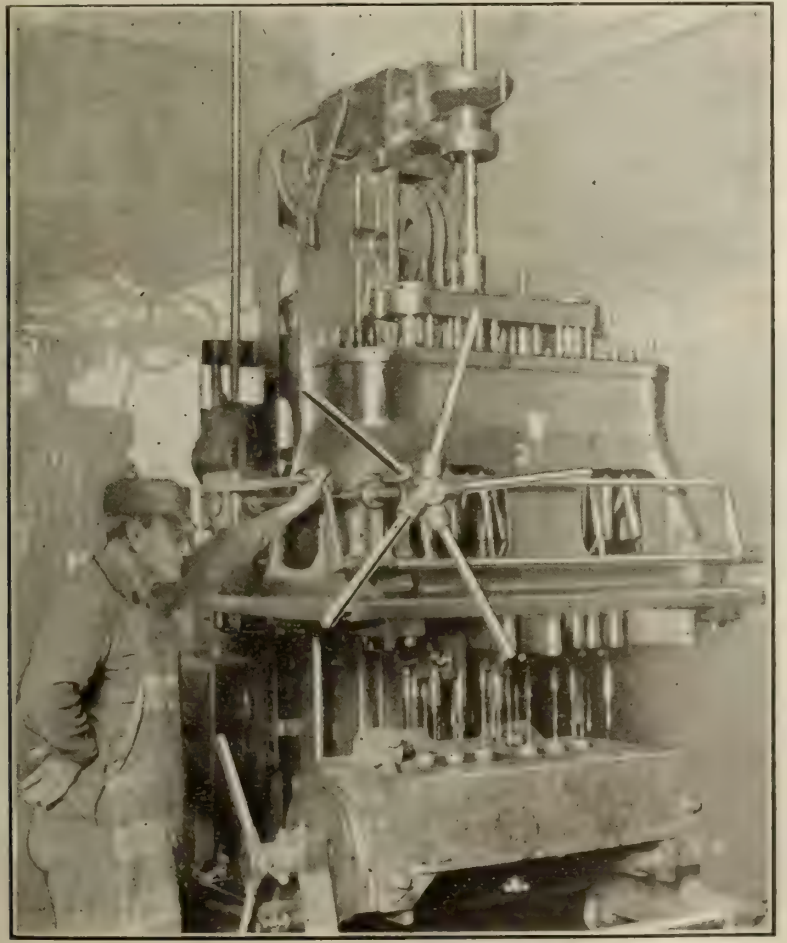

FIG. 8—DRILLING CYLINDER BLOCKS USING A TURNOVER JIG.

Twenty-two holes of ⅜ in. diameter are drilled at one time through switchboard slate panels of various thickness at the Metropolitan Electric Mfg. Co. plant, but no production figure is obtainable in this case. Slate, however, is an awkward material to drill at any time.

Before proceeding to the last example of the present article, we shall digress for a moment in order to touch on a point that so far has not been mentioned, viz.: drill breakage. Owing to the definite feeds existing on such machines there is very little tendency to break the drills, in fact the tendency might well be said not to exist. Carelessness is usually the true cause of drill breakage, but in practically all the examples that have been shown, our information is that drill breakage was practically nil.

No attempt has been made in the preceding examples to show all the lines of drills made by the concern whose machines we show, but we have picked those jobs which we believe will interest our readers. The company manufacture sixteen different types and sizes, ranging from the smallest to the larger styles we have shown, so it will be readily understood why we have confined our illustrations to the number we have.

The concluding example, Fig. 9, shows how the Weeks-Hoffman Co., Syracuse, N. Y., produce their steel drive gears. These gears are 7-16 in. thick, and there are 10 holes in each. The parts are held to .001 in., yet 140 gears are completed every hour. A special revolving table is used, on which are mounted four jigs. In this way the production is practically continuous. This example proves very forcibly our previous statement that to get the most out of a time-saving tool you have to help it all you can by the addition of suitable fixtures.

## LARGE ENGINES.

A British firm has recently equipped itself to supply the mammoth gas engine used to provide the blast for blast-furnaces in iron works. These engines are driven by the gas given off by the blast-furnaces themselves. During the last few years one British firm has supplied large gas engines with a total of about 20,000 horse power.

# Machining a Commutator End Plate for Dynamo

## Part is made from Drop Forging—Punching is First Operation—Automatic is Next Used—Drilling Follows in Due Sequence. Burring and Polishing Completes the Plate.

By ROBERT MAWSON.

AS CAN be readily understood, the machining of a commutator end plate for a lighting dynamo used on automobiles requires extreme care. The important tools used are shown in the present article, and as the part must pass rigid inspection, the jigs, punches, dies, etc., must be of the best.

The piece is made from a drop forging and the first operation is punching three brush plate fastening screw holes. A simple punch and die is used for this work. The end plate is then placed on the punch press, Fig. 1, being located in the die by means of two of the holes, A, into which fit pins that are integral with the tool. The punch, B, attached to the ram of the machine, is then caused to descend and a boss is raised and a hole punched in the piece.

The next illustration, Fig. 2, shows the die with the end plate to be worked upon removed, and gives a better idea of the construction of the tool. The pins, A, are the locating medium as previously noted. The insert, B, is made of hardened tool steel, the upper portion being made with a boss of a similar contour to what is desired to be formed in the piece. At the extreme end the insert is made to form a punch, the purpose of which is to pierce a hole in the end plate. In operation the punch, C, is caused to descend by the machine onto the sliding member, D. As this is forced down it raises the block, E, also the insert, B, as these elements are fastened together with a screw as shown.

As the block and punch insert are raised on the inside of the end plate, a boss is formed and the hole punched. As the punch, C, recedes, the springs shown over the block, E, forces it back to its normal position so that the operator can remove the end plate from the die. The oil hole is then tapped as the next operation, no special tools being required.

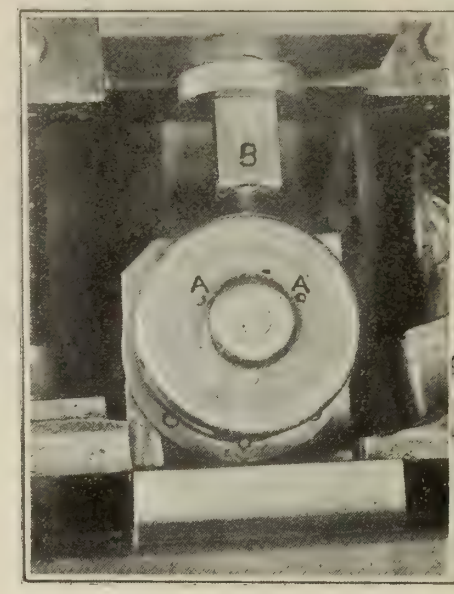

FIG. 1—FORMING BOSS AND PUNCHING HOLE.

FIG. 2—SHOWING THE DIE WITH PIECE REMOVED.

### Boring the Seat

The piece is next placed in the chuck of the automatic, Fig. 3, for the next operation. When in this position the bearing seat is bored and afterwards reamed to size; the end faced; the field frame and brush holder seats bored; the center hole bored and reamed to .609 of an inch; and the outside end cut to length. The various tools used for these operations may be seen in the turret of the machine, the cutting off tool being carried in the cross-slide at the rear. One of the finished parts is shown resting on the turret at A. The piece is then washed in a metal washing machine to remove the grease and dirt.

It is next placed in the jig, Fig. 4, being located by means of a pin, A, which fits into one of the holes punched in the first operation. The open washer, B, is then placed under the head of the binding stud, as shown, and this is drawn back with a nut at the rear of the tool thus holding the part securely.

A hole is then drilled in the piece, the drill being guided through the bushing C, the correct position for the tool being obtained with the projecting pin and stop D. The revolving arbor that carries the piece is then turned on a stud by means of the handle E to the other position, determined by the projecting pin coming against another stop at the rear of the piece and the second hole drilled. These two holes are used for

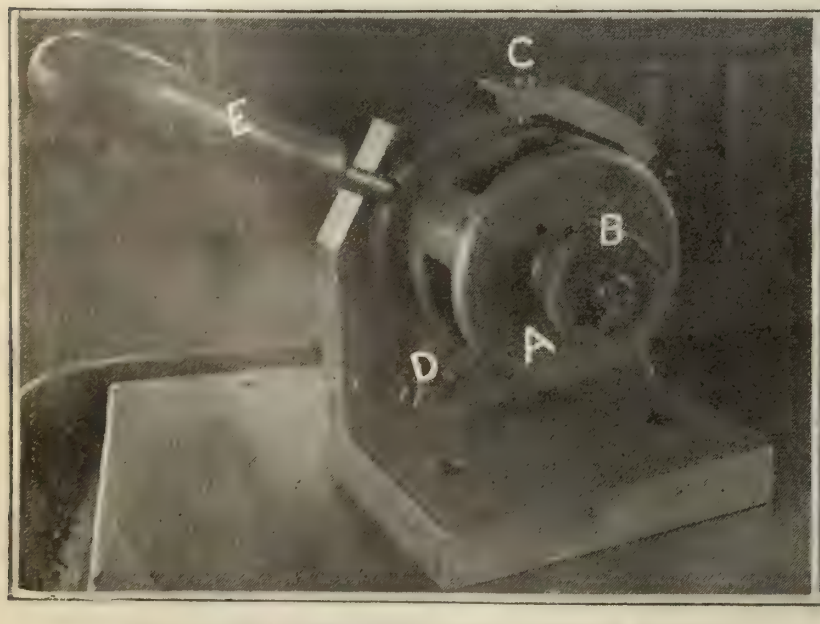

FIG. 4—DRILLING FUSE COVER SCREEN HOLES.

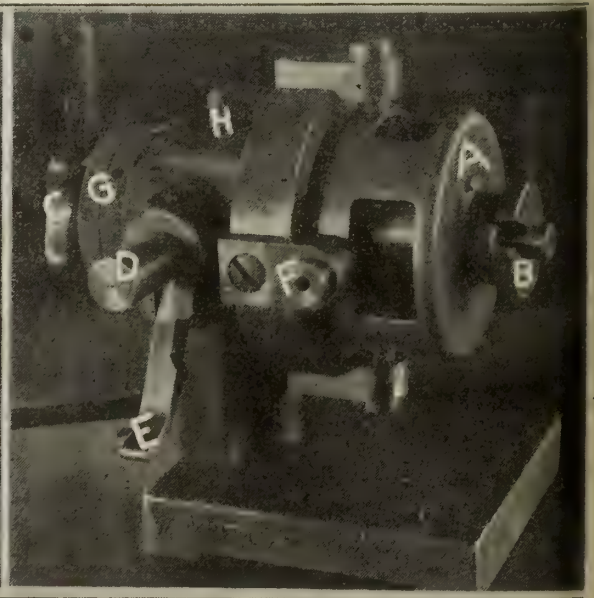

FIG. 5—DRILLING FASTENING SCREW HOLES.

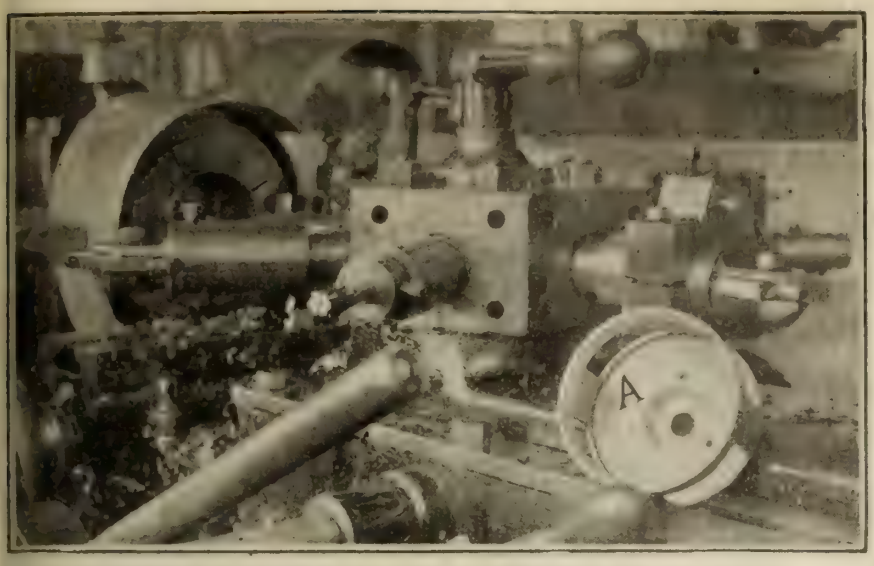

FIG. 3—BORING, REAMING, AND FACING THE WORK.

vetting on the fuse cover to the end late.

### Drilling Operation

The next operation is performed in the g, Fig. 5, being drilling four fasten- ng screw holes used to attach the end late to the frame. The piece is placed n the arbor of the tool and located by eans of the pin A which fits into one f the holes punched in the first opera- on. The open washer, B, is placed nder the shouldered head of the stud s shown, which is then drawn back with ie threaded knob, thus holding it se- urely. The four drilling positions for he tool are obtained by means of the ndex pin D, which fits into holes mach- ned on the periphery of the revolving ember of the jig. To release the pin he operator depresses the lever and this ction pushes out the pin from the locat- ng hole into which it is fitting.

The operator then revolves the jig arbor and the piece to be drilled goes around to the next station when the lever is released, the locating medium dropping into position. The drill is guided through bushings, F.

It will be observed that unusual care has been taken in the design of this tool. The threaded nuts, G, are used to take up any wear which may occur in the revolving member, and an oil cup, H, is also provided to lubricate the same. The two fuse holes drilled in the jig, Fig. 4, are then countersunk on the inside and all other holes burred to remove any projecting edges left by the drills. The piece is then burred on the inside, and the outside polished, afterwards being hot washed to remove grease and dirt. The parts are given a rigid inspection, and, if found correct are transferred to the assembling department, to be attached to the frames after the commutators have been placed into position.

## GOLD MEDAL TO BE AWARDED.

Lt. Col. A. E. White, National Presi- ent of the American Society for Steel reating, has made the announcement hat Prof. H. L. Campbell, 1103 E. Huron t., Ann Arbor, Mich., has been appoint- d Chairman of the Meetings and Papers ommittee of the Society to secure apers for presentation at the Indian- polis Convention and Exhibition to be eld Sept. 19th to 24th, inclusive.

Associated with Prof. Campbell on his committee are: Mr. George O. De- autels, President Imperial Drop Forge o., Indianapolis, Ind.; and Mr. Victor illman, Metallurgist, Crompton & nowles Loom Works, Worcester, Mass.

The Board of Directors has authorized he awarding of a gold medal for the est paper presented at the Indianapolis onvention, and a silver medal for the econd best paper. While the awarding f these medals for this year has been nade to apply to those papers present- d for this year's Convention, the policy n future years will be to award the nedals to the first and second best pap- rs presented before the Society during he year.

Chairman Campbell has just issued a ist of some of the subjects it is proposed o discuss at the Convention, and the 3200 members of the Society have been equested to prepare and submit papers either upon one of the subjects listed be- ow or upon any subject of their own hoosing.

A list of subjects upon which papers will be presented follows:

### General Topics

1.—The Organization and Management of a Heat Treating Department.
2.—Practice of Handling and Check- ing Materials to and from Heat Treating Departments.
3.—Quantity Production Methods for Forging and Heat Treating Tools.
4.—Methods of Heat Treatment of Very Small Machine Parts.
5.—Heat Treatment of Sheet Steel Parts; as Saws, Hack Saw Blades, etc.
6.—The Artificial Seasoning of Hard- ened Steel.
7.—Furnace Design with Reference to Fuel Economy.
8.—Metallography and Its Application.
9.—Comparative Study of Methods for Heating Furnaces by (a) Coal, (b) Fuel Oil, (c) Gas, (d) Electricity.

### Alloy Steels

1.—Topical Discussion of Alloy Steels and Their Heat Treatments for Specific Purposes; as (a) Springs, (b) Gears, (c) Finishing Tools (d) High Speed Cut- ting Tools, (e) Dies.
2.—Practice of Ordering Tool Steel on Specifications.
3.—Cutting Efficiency of High Speed Steel Which Has Received Different Methods of Hardening.
4.—Die Blocks and Their Heat Treat- ment.

### Carburizing

1.—Carburizing Practice Adapted to Alloy Steel Parts.
2.—Determination of Unit Cost of Car- burizing Steel Parts.
3.—Efficiencies of Different Mixtures for Cyanide Hardening.
4.—Practice of Cyanide Hardening.
5.—The Service of Annealing Boxes Made of Different Materials.

## STAINLESS STEEL.

In a paper presented at the Phila- delphia convention of the American So- ciety for Steel Treating, W. H. Marble gave the following standard analysis for stainless steel:—

| | |
|---|---|
| Carbon | 0.20 to 0.40%. |
| Chromium | 11.40 to 14%. |
| Manganese | Not to exceed 0.50%. |
| Silicon | Not to exceed 0.30%. |
| Sulphur and phosphorus | As low as possible. |

It is manufactured in either the cruci- ble or the electric furnace, the process being similar to that employed for high- speed steel, which it resembles in a number of properties, particularly in being air-hardening.

For the higher heats, temper- colours appear at about twice the temperature for ordinary tool-steel, making temper- ing by temperature rather than by color particularly important. Up to a tem- perature of about 1520° F. the gloss- surface caused by polishing and hot- tinting is permanent, and the specimen neither gains nor loses appreciably in weight. The alloy's power to resist cor- rosion is not caused by any finish ap- plied by the manufacturer, but by the properties of the steel itself. No mat- ter how rough the surface of a hardened and tempered article may be, if it is a clean metallic surface and has not been distorted, it will be rustless. However, to exercise this feature to the best ad- vantage, a really good ground polished surface should be provided.

Stainless steel does not corrode when in contact with other steel. It is, how- ever, attacked in an otherwise non-cor- roding liquid when in direct metallic contact with copper or other alloys, such as gunmetal. Cold-working des- troys its stainless property, therefore cold-pressed parts should be heat- treated.

Although the principal applications of this alloy have so far been for cutlery and valves, there are many other possi- ble uses. Its easy machinability makes possible its use for many purposes for which high-nickel steels are now em- ployed, these steels being difficult to machine. As stainless steel is hard to deform, and is not easily eroded at tem- peratures up to 1520° F., it is a good material for hot-dies, extrusion-dies, punches, and for moulds for die-cast- ings. Other possible uses include tur- bine-blades, pump-rods and valves, acid- pumps, rams, evaporating-pans, races and rollers for ball bearings, and re- frigerator machinery. Turbine and pump parts made with this alloy have remained bright, with an inappreciable amount of corrosion, after having been in use for several years. On account of its toughness, ability to resist abra- sion, and mirror-like finish, moving parts made of this alloy wear longer than if made of other materials, and because of the reduced amount of fric- tion require less repacking.

# Proper Accident Prevention Pays Large Return

## Usually Four Stipulations Confront An Engineer When He is Making Safety Plans for a Plant—Safeguarding The Immediate Work of the Operator—The Real Trouble with Circular Saws

By C. P. TOLMAN

PROPERLY conducted accident prevention work pays a larger return on investment and operating cost than any other department of the ordinary industrial plant." This sounds like a rather sweeping statement, but in his address before the joint meeting of the Cleveland Engineering Society, and the Engineering Section of the National Safety Council, C. P. Tolman, chief engineer and chairman, Manufacturing Committee, National Lead Co., and president National Safety Council, stated that from carefully recorded data, the reduction in accidents of eight well known companies employing some 36,200, had been reduced over 70 per cent. He also told the following stories:

A certain small company operating a coal mine with 100 men reduced accident cost per ton, 68 per cent., while a larger corporation made a profit from its safety work of $1,000,000 per year. These are not suppositions, but actual figures, and as Mr. Tolman says, "They tell us nothing of the incidental profits from better relations between men and management, and give no credit for the saving of human life and suffering."

"Usually the engineer find for his problem a plant equipped and operating. He is required to make it as safe as possible with the following stipulations: (a) He must not interrupt operations; (b) He must do nothing which would decrease output or increase cost; (c) He must not make changes of a character or in a manner to cause labor trouble; (d) He must not make changes which will affect the character of the product; otherwise he has free rein.

This seems to leave little chance for accomplishment. But hundreds of engineers are doing effective safety work under just such restrictions. The work is limited of course to the more common measures, such as guarding machines and transmissions, general betterment of of ventilation, lighting and floor conditions; etc. It is well worth while, profitable to the industry, and calls for real ability. The design of a gear guard is not beneath professional dignity. A gear guard which answers all requirements satisfactorily calls for skillful design.

Among other requirements we have, for example, the following: (a) It must be securely attached; (b) It must be readily opened or removed; (c) It should be easier to close it than to leave it open; (d) It must not interfere with oiling or adjustment of the machine; (e) It should not drip oil or grease on the floor to make a slipping hazard; (f) It should be designed for economical manufacture; (g) The means for attaching and opening should be of a kind familiar or obvious to the average workman; (h) Insofar as possible, it should permit inspection of gears without opening or removing. Properly designed guards may save considerable in first cost, will save much in maintenance, and will remain in use. Improperly designed guards may not afford proper protection, and, if awkward to replace, are usually left of, once they have been removed.

Leaving the more obvious measure incidental to safeguarding machinery, let us consider the less obvious measures for safegurading the immediate work of the operator. At once we are in a much more profitable field of work. Most of the profit in the earlier class comes through saving in cost through the prevention of accidents, whereas in the latter class, by bettering operation from the safety standpoint, we not only reduce accident cost, but if our work is properly done we invariably increase production or save waste. As an example of the latter, in the white lead industry portable dust collectors were developed and used for sanitary reasons. Purely out of curiosity the lead dust saved was weighed. The average of all factories showed a saving of lead amounting to a return of over 30 per cent. on the investment.

As an example of increased production:—In the manufacture of steel drums, using toggle drawing presses, a factory was started about ten years ago with presses operating ten strokes a minute. At this rate the loss of fingers was alarming. The presses were therefore slowed down to seven strokes a minute. The accidents were reduced, but still were serious. The superintendent then devised and installed a method of operating the clutch by a solenoid magnet. The electric circuit led through two switches connected in series. These switches were arranged to open by springs and be closed by hand. One switch was located on each side of the press frame. To operate the press the workman had to use one hand on each switch. He could not get his hand or fingers in the press while it was operating. The presses were then speeded up to twelve strokes per minute, making an increase in production of 70 per cent with safe operation.

This is not an unusual case. Semi automatic press feeds will, while making the operation safe, increase output from 10 to 100 per cent. Full automatic feed will better this. Ejectors or kick-out give similar results. Lest we get the impression that results of this sort are confined to punch presses, suppose we consider another class of machinery in famous for mutilation of hands, the circular saw.

### The Circular Saw

At the National Safety Council's Congress in Milwaukee last year, during session of the Engineering Section it developed that 70 per cent. of saw accident originate in bad condition of the saw-dull, not properly set, or not properly gummed. There were men present ranging from youth to rugged age, who had lived with woodworking machinery, and they were unanimous on this point. They were then asked if saws and other woodworking machinery were kept in proper condition as compared with the average condition, what increase in production would result. Again they agreed—at least 20 per cent. In other words, by keeping the saws in reasonable order the average woodworking plant would eliminate the source of 70 per cent. of saw accidents and make a net gain of 20 per cent. in production with the same equipment, the same labor, and less power.

Once again that we may remember we are dealing with a broad general principle and not with any one class of machinery, let us consider the machine shop. Here we have the usual groups of accidents: (a) The kind which may befall any workman; (b) Selective accidents: those select the careless, indifferent, or ignorant workman, or that select the best of the mechanics.

Aside from the labor turnover this last is a pretty serious proposition. The statement that there is a type of accident which selects your best men requires some proof. The best known example of this type happens when your machinist uses his hand as a brake on the rim of the face plate of his lathe. The man who does this is the man who wants to see his work progress. He is not content to stand idle while his lathe comes slowly to rest. He wants to get his micrometer on the work and see the result of the cut—to get the piece out when finished, and get in the next one. So he disobeys orders—he does just what you or I would do—he is interested in his job and he takes the chance. This hazard can be wiped out. The correction measure involves an important fundamental principle in safety work.

### Do It the Safe Way

In this case the thing to be done is stop the lathe. The power must first shut off. The remedy is obvious. Equip the lathe with a brake; if it is a belt driven lathe, use a foot pedal which when pressed first shuts off the power

**PROBLEMS TO MEET.**

Usually the engineer finds for his problem a plant equipped and operating. He is required to make it as safe as possible with the following stipulations.

He must not interrupt operations.

He must do nothing which would decrease output or increase cost.

He must not make changes of a character or in a manner to cause labor trouble.

He must not make changes which will effect the character of the product; otherwise he has free rein.

On the face of it, these restrictions would seem to bar safety engineers from accomplishing much, yet hundreds of engineers are accomplishing wonderful results under such restrictions.

An engineer preparing for safety work must become familiar with organized safety work and the practical data which has been patiently accumulated in the course of such work. He must respond to the spirit of the safety movement for data alone will not serve him.

and then applies the brake. The almost instantaneous effect of the powerful foot brake leaves no incentive to use the hand on the face plate. If the lathe is direct motor driven, use a controller designed for dynamic braking.

The International Harvester Company, at its Milwaukee shops, equipped the spinning lathes with foot brakes as described. The accident hazard was eliminated and the increased production is paying an enormous return compared to the cost of this home-made attachment.

Gratifying as are the results from careful analysis and treatment of hazards where found in a growing plant, there is another broader fundamental method of treatment which is occasionally open to the engineer where a new plant is being built. Shall we digress a moment to make the principle clear by an illustration. The personal experience I am going to relate is one you have all had. Recently I visited a plant for which an expensive addition was being planned. Upon going through the plant I found an unusual equipment of machinery specially designed for the work. The machines, although performing what would be considered difficult operations, were simple in that way which speaks the genius of the designer. But the arrangement of the machines was haphazard. Additions had been made from time to time and original "flow sheet" was lost to view. Had the designer of the machines viewed his whole plant as one great machine, he would have done with it as he had done with the individual machines, and the additional building, machinery and labor would not be needed. This is the general opinion of engineering revision as applied to safety: Regard the whole plant as a machine. Make the whole, as well as each part, function for safety. The production returns incidental to safe methods for the individual machine are multiplied again when the whole plant is co-ordinated on a safety basis.

Provision for clear aisles is a safety measure. It also facilitates transfer of materials and lowers production costs. Racks and bins properly placed reduce accidents from falling objects; they also save material from injury and facilitate production. Correct lighting equipment and correct location of machines with respect to natural light prevent eye strain; waste from faulty manufacture is also saved, and production increased.

Grouping equipment involving special hazards or bad working conditions make it possible to treat these conditions effectively, and avoid exposure of other employees than those engaged in the particular work. For example, furnaces so grouped can be hooded to carry off heat and fumes; special cool air supply can be provided. The advantages of grouping apply also when chemicals are used or dusty operations are involved. While some of these measures can be applied to a degree regardless of general plant arrangment, all of them can be applied much more effectively if it is feasible to treat the plant as a whole.

With the growth of an industry in volume it is usual to add more and more of the small capacity units which, although suitable as to capacity in the earlier days, have been outgrown, and too many units are needed to produce the output. It is engineering revision in respect to the custom of such an industry to redesign such equipment, increasing the capacity of the unit. The reduction of hazard is two-fold when this is done—first, there are fewer men exposed; second, in redesigning, the equipment can always b made inherently safer, and the reduction in manufacturing cost is obviously large.

In the steel industry we have a strik-example of just such revision. It is sometimes possible to make radical changes in the general process of manufacture avoiding hazardous features and effecting large economies in operating cost. This is all work for the engineer, some phases of it calling for broader training and experience than others. To do any of it thoroughly and well we must include that factor which we have thus far omitted, the human equasion. The engineer preparing for this work must become familiar with organized safety work and the practical data which has been patiently accumulated in the course of such work. He must respond to the spirit of the safety movement, for words and data alone will not serve him. I have tried thus far to establish in your minds two basic principles: Properly conducted accident prevention work pays a larger return on investment and operating cost than any department of the ordinary industrial plant, and that you should make it easier and most effective to do it the safe way.

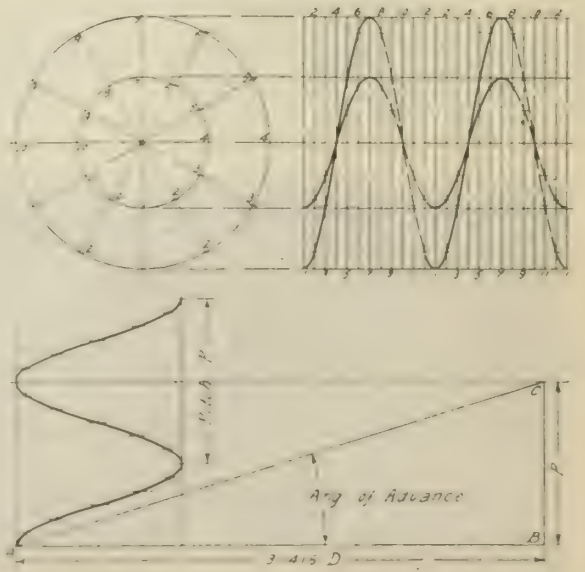
I have shown you the opportunity for the engineer in this field of work. I do not mean that he is forthwith to christen himself safety engineer. On the contrary, he is not true to the ethics of his profession or to the interest of his client, if, knowing the effectiveness of the safety viewpoint, he fails to make safety a part of his professional attitude towards all his work. The untiring effort of hundreds of men during the last nine years has built up an organization for the advancement of safety through the interchange of ideas."

### MELTING ELECTRIC FURNACE.

An interesting new type of electric furnace for brass-melting has been perfected by a British firm. Its main feature is the practically indestructible character of the heating elements. They are of the resistance type and do not oxidize. Several years of invention and experiment were occupied in achieving this result, which abolishes all maintenance costs on the furnace. Three of these furnaces are in operation, each of 100 kilogrammes capacity and each taking 25 units of electricity. A charge of brass is melted every hour, with a consumption of 300 units of electricity per ton. The lining of the furnace can be used for years without renewal, so that practically the only cost is for electricity and labor.

### OIL ENGINE BOOK.

Vickers-Petters, Limited, of Ipswick, England, has recently issued a new catalogue featuring their stationary and marine types of oil engines for working on crude and residual oils or refined petroleum, in capacities of from 10 to 450 brake horse power. The 50-page, 8 by 10 booklet illustrates and describes a large number of these engines, setting forth many of the advantages and details of construction. Vickers-Petters are represented in Canada by R. S. Griffith, 371 St. James St., Montreal.



# *Screw Threads*

## *Developing the Helix*

As all screw threads are based on the curve called the helix, a knowledge of its construction should be acquired. The helix is a uniformly advancing curve around the circumference of a cylinder, one complete turn being designated as the pitch. This curve developed on a flat surface would be represented by the straight line A C, which forms the hypotenuse of a right-angled triangle, the base A B being the length of the circumference, and the height B C the pitch of the helix, the inclination of the curve being the angle B A C.

A graphical construction of the curve is shown above. A circle of the required diameter is first drawn and divided into any number of equal parts. A rectangle is projected to one side and the pitch distance on the horizontal lines divided into as many equal parts as the adjoining circle. These divisions are numbered as shown and the intersection of corresponding lines determines the path of the helix. The more divisions the greater accuracy.

It will be noted that for the same pitch the smaller diameters have the greater angle of advance.

# Steel Belting As a Means of Transmission

## Material Used on Such Belts is a Carefully Hardened Charcoal Steel—Process of Preparation a Secret—Claims Made for This Belting—Safeguards—Stories of Installations

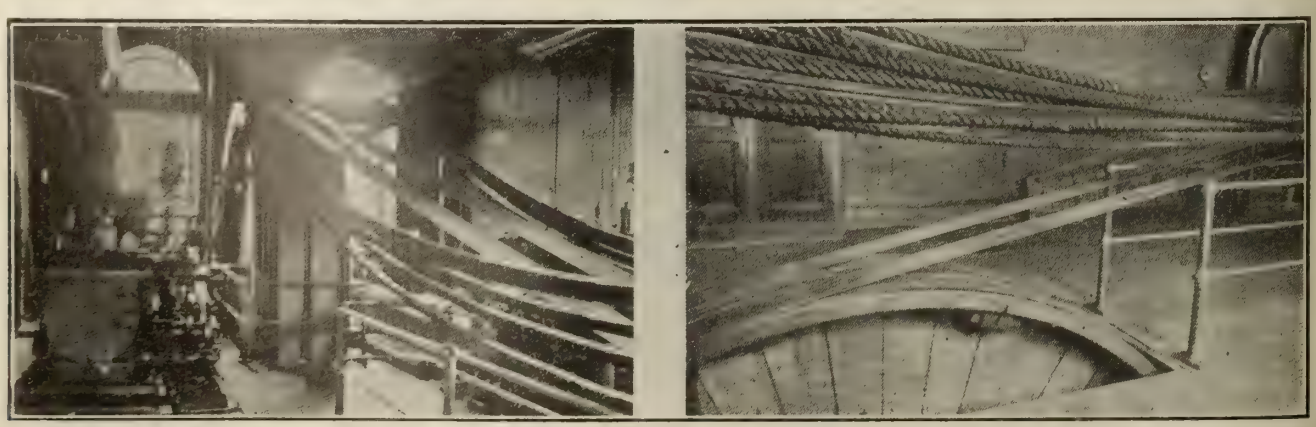
THE LOSS in power in transmission from the engine, whether steam or electrical, to the point of application is a difficulty which has always exercised the minds of engineers wherever mechanical power is used. Experimental attempts were made in employing driving belts of metal, but, after a short period of use they invariably broke when subjected to any considerable increase in load. Persistent failure also attached itself to the various connections used in joining the ends of the bands together. Subsequent experiments showed that these unsatisfactory results were attributable mainly to mistaken conceptions as to the conditions under which steel bands should be used. In previous experiments it was found that consideration was not given to the fact that the metal belt employed is subjected to a flexure constantly varying from zero to a maximum, and that to ensure durability with such a demand it was not sufficient for the belts to be calculated in the usual manner. The error consisted in not regarding the result of philosophical researches first undertaken by Wohler, according to which a tension constantly varying from zero value to a maximum and frequently applied to a body causes self destruction if the maximum tension is not confined to half the breaking stress of the material.

The present system is therefore based on the knowledge that a fracture of the belt even with a constantly varying demand on its flexibility can be avoided with certainty if the maximum demand likely to occur is kept so low that it does not attain half the value of the limit of fracture. Exhaustive series of trials have been carried out in England. According to the present method the breaking of belts is avoided, and the durability made unlimited by the thickness.

It was found that owing to the high modulus of elasticity of steel that it was very necessary to determine the length of a driving belt with considerable accuracy; a short extension compelled by cutting the belt too short in the first instance set up very serious stresses. To accomplish this purpose an ingenious device has been invented for determining the necessary length for the purpose of obtaining a truly correct working tension.

IN THIS CASE THREE 8 IN. STEEL BELTS REPLACED FOURTEEN 1¾ IN. ROPES. THE PULLEYS ARE 5 FT. 6 IN. EACH, AND THE SHAFT CENTERS 20 FT. 8½ IN. THE VELOCITY IS 2,400 FT. PER MINUTE, AND THE H.P. 340. THE BELTS RUN AT 142 R.P.M. THE DRIVE HAS BEEN IN USE SINCE 1915.

In the patented joint clamping plates are shaped to suit the pulley profile, stresses at the joint are distributed evenly over the whole width, and one of the most prolific causes of fracture in the early installations is thus avoided.



The material used is a carefully hardened charcoal steel, prepared by a secret process, rough rolled at a red heat, and then brought to 0.2 to 0.9 mm. thickness and 12 to 200 m. m. in width by cold working. The tensile strength of the finished material is about 95 tons to the square inch. The edges are rounded and finely finished, so enabling the belt to be safely handled even when running at high velocity. The elasticity remains unimpaired with use.

### Friction Covering on Pulleys

So that metal does not run to metal and to prevent any possible slip, a friction coating consisting of a layer of canvas, to which is glued fine sheets of cork, is placed over the pulley rim, and to avoid stripping under variable load the pulley rim is first serrated by a rough file or chisel nuts. A special cement is available for use in very damp situations.

It is claimed that steel belts have replaced cotton rope drives in a number of cases and that the simplicity of the conversion is such that the conversion of a complete rope race can be undertaken on a Saturday noon and be completed with the steel belts ready for running the following Monday morning. The conversion is said to usually increase the horse power available at the driven shaft by 7 to 25 per cent., this being the result of a number of tests in actual installations. Where space is cramped and drives are running to various floors, steel driving belts are said to be very adaptable.

The requirements necessary to the successful employment of steel belt transmission are simple, but neverthe-

A 450 H.P. DRIVE. SHAFT CENTERS ARE 40 FT. 3 IN. PULLEY DIAMETERS 15 FT. 2 IN., AND 12 FT. 7½ IN. TWO 8 IN. STEEL BELTS REPLACED ELEVEN 1¾ IN. ROPES. THE SPEED RANGES FROM 70 TO 90 R.P.M. THIS DRIVE HAS BEEN IN USE SINCE 1915.

less important, and given suitable conditions, the results are definite and certain. When it is understood that steel belts must run perfectly true on to the pulleys, the tension to remain exactly as when fitted, the conditions demanded will be easily comprehended. The shafts, bearings and fixings must be of a solid construction, strong enough to transmit the maximum load demanded. The shafts must also be parallel, and the pulleys running true, and without vibration.

It should be clearly understood that the steel belt is only a part of what actually is a highly scientific system of power transmission. As already explained, the process of preparing the steel and the mounting of the belts is carried out on highly scientific lines.

### Safeguards

With ordinary care steel belts are perfectly safe, as in case of fracture the belts will not fly, but fall between the shafts. The edges are rounded, and can be handled whilst running. In every country where used they are placed under precisely the same laws and regulations as applied to ropes or leather belts.

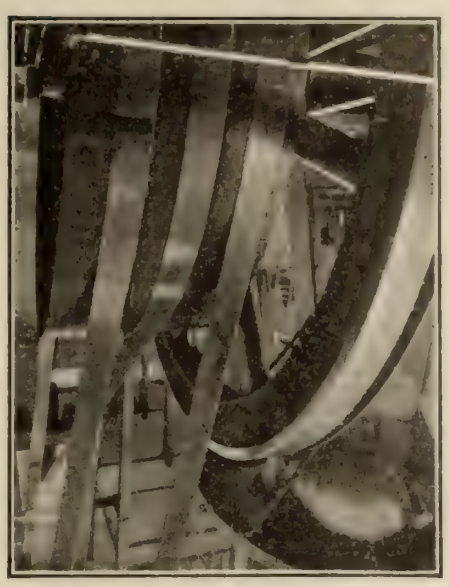
Here are a few claims made by the makers of the type of belt we have been describing:

An efficiency in power delivery of 99-99½ per cent. Great steadiness: a necessity for electrical machinery, textile purposes, paper mills, etc. A perpendicular drive is no disadvantage for steel belt driving.

Absence of stretching—a steel belt does not stretch by use, as has been seen by eight years' experience. Even running, free from slip.—As there is no actual measurable slip, it follows that transmission by steel belts is uniform and invariable.

Great power under present conditions. —In cases where the pulleys are limited in size it is often possible to get an increased power transmitted by the use of steel belts without any re-arrangement.

Cool bearings.—Owing to the exact calculations of the necessary tension for each particular drive, together with the great reduction in the weight of steel belt. Cleanliness.—No messy dressings are required.



Unwearability. — Steel driving belts have now been in operation for eight years, and tests made of the belts first fitted show no signs of deterioration whatever. It seems evident therefore that the life of the steel belt is unlimited.

### Breakages

Where the conditions are in accordance with the requirements, it is only in very isolated instances in which a fracture occurs. These instances are invariably due to a flaw in the material itself, and will show within the first eight weeks of running; by this is meant that if a steel belt runs for eight weeks it is a practical certainty that it is free from flaw and will run indefinitely. To cover any serious stoppage caused by a faulty belt, the manufacturers will, if requested, supply with every drive a duplicate or reserve belt, measured and ready for immediate fitting.

Steel belts vary in width from 2½ in. to 10 in., and thickness 0.4 m. m. to 1.0 m. m.

Several steel belt drives are performing good service in England where there are over 50,000 H. P. varying from 20 to over 800 H. P. drives in successful operation, some of these steel belt drives having been in operation over eight years. As steel belts may be applied in multiples there is no limit to the possible power to be transmitted.

ANOTHER COMPACT STEEL BELT DRIVE.

## INCLINING TORCH WHEN CUTTING

Straightaway cutting with the hand torch is facilitated by inclining the head of the torch backward after the cut is well started. The degree of inclination will vary somewhat with the thickness of the metal and other conditions. A fairly conservative figure is 65 to 75 degrees angle from the plate behind the torch to the torch head. The effect of inclining the torch is to speed up cutting considerably. The gases directed at an angle preheat the thin edge of the undercut metal ahead of the igniting temperature more rapidly than when the tip is held squarely with the plate. The gases and products of combustion turn backward, passing through an arc of say, approximately, 90 degrees and shooting down and back. Often the drag or lag of the cut will be as much as one-half or even three-quarters inch on half-inch steel. When cutting with the torch inclined it should be uprighted just before finishing the cut in order to sever the metal at the end. Otherwise a wedge of uncut metal will be left due to the oxygen's shooting by the corner as the torch reaches the end of the cut. The "drag" part of the cut will be left untouched. Uprighting of the torch cuts this portion off cleanly and lets the piece drop.

Expert hand cutters are able to cut one-half inch steel plate with a very narrow kerf and low oxygen pressure, often working at speeds up to 24 inches per minute and sometimes faster. The experienced cutter learns to follow the cut with great precision, going no faster than permissible but still following the combustion rate so closely that there is little or no loss of cutting efficiency. This is very important. The cutter who tries to work too fast "loses the cut" and makes a mess of things. The cutter who works too slowly wastes gas and time, while the one who knows just how fast to cut approximates 100 per cent. efficiency in time and gas.—Antogenous Welding.

## REMOVING BUCKLES IN PLATES

When a section of a steel plate is heated with the oxy-acetylene torch, expansion of the heated metal is restrained by the surrounding cold metal, the result being that the hot metal is slightly upset and made a little thicker. When the metal cools it shrinks, continues Acetylene Journal, and advantage of this is taken to remove buckles from plates. Buckles can be eliminated very nicely with the torch by operators who understand the mechanics of the trick. The buckle should be located closely and circled with chalk. Three or four spots should be marked, depending on the size of the buckle and the thickness of the metal. Heating the spots results in the complete disappearance of the buckle, due to the upsetting and subsequent contraction of the metal. It might be explained that a buckle in a plate is simply a result of excess metal at that place. When the metal is shrunk the buckle lies flat.

The operation has been found to be easy in accomplishment, and invariably satisfactory in the desired result.

## A CHAIN FRACTURE

Last autumn an explosion occurred on an oil tank barge on the Thames. In the official report there is a description of how a chain broke, which gives some indication as to how great may be the forces thus produced and how suddenly they may be applied.

The chain in question was a set of 1½ in. chain slings and a large ring suspended from a set of sheer legs. After the explosion some of the links of the chain were missing and others fractured. Shackle pins were also missing or distorted, and the large top ring, of 3½ in. metal and 12 in. inside diameter, was cracked diametrically, but not appreciably distorted. The condition of the various fractures, etc., indicated that the slings had been subjected to very severe stresses suddenly applied. There is conclusive evidence that before the explosion the ends of the slings were resting upon the port side of the top of the tank, but they were not secured to any part of the tank or barge. The depressions noted near the rugged hole in the tank top were such as might have been produced by a very violent blow on the plate from the rounded ends of heavy chain links or shackles. The metal at the edges of the hole was bent inwards, and this effect would be produced by the resistance which would be offered by heavy slings and the plate beneath them to the force of an explosion within the tank. It appears, therefore, that the ends of the slings penetrated the tank top owing to the violent upward movement of the latter, and, as the whole of the tank top was ripped up along the port side and turned over from the port to the starboard side, the slings caught in the ragged metal of the hole, and in this way were subjected to a tremendous sudden jerk which caused the fractures in the chain links and ring. It is estimated that a total pull of at least 135 tons was necessary to fracture the large ring.

---

The mechanical properties of medium carbon steel are changed but little by a wide variety of rolling conditions, according to the Bureau of Standards

# Method of Training Machine Shop Workers

## Training Department A Progressive Step—Equipment Provided—Old and New Method of Induction—Pieces Produced are Counted Several Times Each Day and Student Has Chance To Judge His Own Progress

By GEORGE A. SEYLER

SPEAKING on the subject of "Training Machine Shop Workers," the author, who is works manager of the Lunkenheimer Co., Cincinnati, Ohio, had the following to relate to the National Metal Trades Association:

During the machinists' strike in Cincinnati last year it was necessary to induct new workmen into the shops to fill vacancies, and after giving the subject careful thought the decision was reached to install a training department in the plant of the Lunkenheimer Co. After an experience of eight months with the department and careful observation of the graduates and their wrok, the plan has proved to be one of the most progressive steps ever taken in our plant.

To determine the required number of men to supply a 100 per cent. turnover, it was found necessary to create a training department of sufficient size and with proper equipment to graduate 10 men per week, to maintain a force of approximately 500 men in the several manufacturing departments. It was assumed that the average period of training would be not longer than two weeks, the idea being to train specialized operators and not to teach apprenticeship courses.

The proper equipment of a training department should be based, first, upon the nature of the work in which the students are to be trained, and, second, on the desired number of students to be kept in training, together with the length of time required to obtain necessary efficiency to graduate or promote the students to regular production work.

### Equipment Provided

The equipment provided for our training department comprised the following: One testing apparatus, to be manned by two men; one boring mill, one speed lathe, one punch press, two drill presses, five monitor lathes of various sizes, one heavy duty production lathe, one hand screw machine, one forming lathe, one hand-operated two-spindle milling machine, one air-operated two-spindle milling machine and an assembly bench, with ample space and equipment for four men.

In selecting a location it was decided to isolate the training department from the production departments. Students have their own workroom and locker room and do not come in contact with any of the workmen until they graduate into the main shops.

Under the old method of inducting new workers into the shops, a beginner is required to gain a great amount of knowledge and information in very short time. Upon entering the employment department he is interviewed by the employment manager and required to give the following information: Name, address, date of birth, nationality, married or single, number of dependants, and possibly to answer other questions.

He is then told about the plan whereby every employee is insured by the company. He is told the number of his registration card on the time clock and is given a key for his locker. He is escorted to the time clock and instructed how to register in the morning, noon and night. He is taken to the locker room and shown the location of his locker. Next he is to escorted to the department in which he is to work. He is introduced to the foreman, who presents him to the assistant foreman, who in turn takes him to his machine or bench and tells him his machine and tool check numbers.

The man is ready to work, but his head is crammed with preliminary instructions, locations, numbers, names, etc. Sense of location is lost, he has forgotten the name of his foreman and possibly the number of his locker, and while racking his brains in a futile endeavor to remember these things he is being given instructions in the use, setup and oiling of his machine. Perhaps all this has taken place in less than an hour. In the meantime, he has become confused with the vision before him, the maze of wheels and belts, and is trying to find his bearings by glancing at some of the workmen near him. Perhaps in a few hours' time he will be left alone to try his own hand at producing, and observing the regularity of production by the fellow next to him and comparing that with his own small output, he begins to feel that he won't be able to make good. When the signal sounds for the lunch hour at noon we might find him devising ways and means of getting out of the shop. Now, as for the induction of a man into our training department: After his interview with the employment manager, he is turned over to the director of training who puts him at his ease. The director is able to speak to him in a moderate, pleasing tone as it is not necessary to shout to be heard above the din of machinery, as in the main shop. He does not bother the man about his registration card as this matter has been attended to for him. He also gives him a memorandum card upon which is written the clock number, locker key number and machine number, and tells him to carry this with him to remind him of the numbers. He is extremely careful not to crowd the new man with too many impressions, realizing that it is futile to begin teaching additional points until the first have been assimilated. There is no confusion in the beginner's mind, he is informed that everyone else in this department is undergoing training.

### New Plan Proves Superior

Under the old method of inducting a worker into the shops, he was instructed in each step as he progressed by the simple means of being told what to do; he followed out a series of commands to do this first, then that, then the other thing, and so on. The instructor, after giving about 15 or 20 direct commands, usually asked the question "Do you understand?" The new workman, for fear of being criticized or being judged as dense would answer "Yes." It is possible for a man to mimic perhaps 10 or 12 motions. He is able to reduce them to a habit and thereby pass muster as a man who will "pick up," during which time he forms bad habits of posture and manipulation of his implements which take months to correct.

Without proper training, a beginne in many instances, following the line o least resistance, or through fear of be ing reprimanded, will turn to the ma working next to him for help.

This action immediately establishes bond between the two men which ma work to the material disadvantage of the beginner, especially if the "old hand' might be radical or tricky. The best friends of the beginner in the shop are the director of training and his assistants, to whom the student may appeal at any time for additional instruction. These men think straight and are able not only to teach and instruct the beginner in the manipulation and handling of his machine or tools, but also to give him a viewpoint that is extremely difficult to be overcome by the soap-box agitator.

One of the principles in a training department is that a man learns by doing. It is not necessary for an instructor to touch a machine when training a student, but he can have the student do all the work himself, providing the instructor can teach by means of reasoning each step as they progress.

Suppose you were called upon to teach a man to operate a lathe. Where would you begin? With the shifter or with the tool and the tool-post, tail stock, lead screw, or spindle, or like a great many instructors, would you teach a little of this and a little of that? The effect on a pupil being taught by an instructor who has not analyzed a progressive method of teaching is like reading a magazine or a book wherein the pages fail to come in regular sequence.

To discover whether or not a student is reasoning during the process of teaching, it is necessary to know what is going on in his mind, and the way to find this out is to ask a question that will make him think in order to give a proper answer. The question "Do you understand?" with the answer "Yes" or "No," does not mean anything, but the question "Why did you push that lever?" causes the student to think, to give a reason for his action.

The number of pieces of work produced each half-hour is counted for the student and registered on a card, and he is able 16 times a day to judge his own progress. From our experience it is found that 75 per cent. of the students can reach a given standard of production in about 10 days, and during the balance of the second week of training this standard is maintained or even bettered.

Since its installation last fall, more than 80 men have passed through our training department. We have found but two who did not fit in and had to be dismissed because they lacked latent mechanical ability. Of the balance who graduated from the department six have left our employ. As a part of the routine the graduates are brought to the office of the works manager for a little personal talk, and they consider it a privilege to go up into the main shops. Incidentally they find that the "bosses" are human beings like themselves.

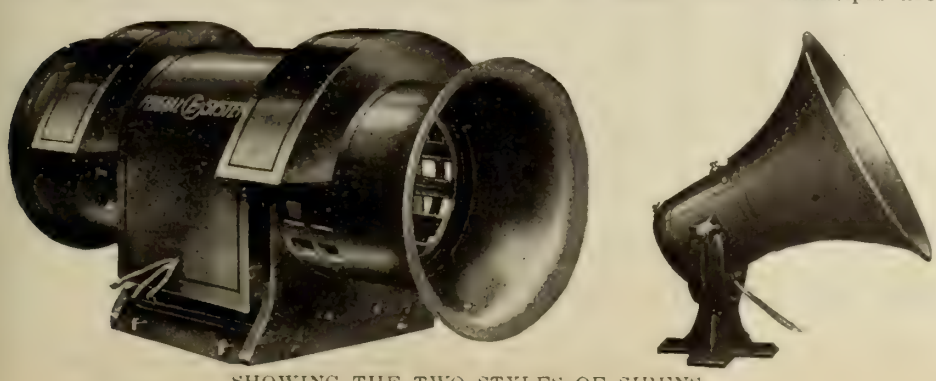
After 10 of these graduates had been placed on production in various departments of the main shops, inquiry was made of the foremen as to their opinion of them. In every case the opinion was that the employment manager had selected extraordinary men for training. The standard of intelligence and efficiency had shown such marked improvement the foremen concluded that in the past the employment department had provided them with men of the poorest quality obtainable. The foremen were then asked as to how the students qualified in comparison with men trained in the production shop under old methods and the answers were that the students at the time of entering the shops were equal to men who had been working in the shops from six to nine months. New high records were made by some of the students from the training department within a short time after being put on production work.

Appreciating the many advantages in training men for production, the thought was impressed upon our minds that the function of the training department, its equipment and organization could be extended by giving the assistant foremen what might be called a post-graduate course. This training is now in progress and the results are most encouraging. Thirty-six assistant foremen are in training, divided into classes of six each, each class having an hour's instruction during the day. Two nights per week are devoted to class ensemble, under the direction of an assistant professor of the University of Cincinnati. The attendance is purely voluntary on the part of those enrolling. The night classes as a rule extend beyond the time allotted, due entirely to the enthusiasm and interest of those attending.

# The Use of Sirens in Industrial Plants

*By O. S. BURKE

THE USE of electric sirens as a means of fire protection in industrial plants is extending more and more every day as their varied and unique value is appreciated. One of the siren's outstanding dominant or predominant qualities is its clear, shrill, penetrating sound which cannot be confused with any other signal, and which is easily distinguished above the roar of machinery in industrial plants. When located outside, sirens can be heard for miles around.



Another great advantage of the siren as a fire signal and alarm device is that it may be set in motion from as many different places as desired by merely pushing a button. Furthermore, it can be arranged so as to give signals indicating the location of a fire within the plant instead of giving only a general alarm. Electric sirens are built in various sizes, the larger being commonly known as single head, and double head, meaning that one size has one large rotor only, while a larger size has a larger rotor on each end of the machine, the motor being in the middle. It can easily be seen that the larger siren will have a much further penetrating power. Because of the fact that these style sirens are used primarily for exterior use, they are absolutely weatherproof.

An occasional oiling is all that is necessary to keep them running smoothly year in and year out—they require little or no attention, and the cost of operation is really negligible, rarely more than two or three dollars a year. In large industrial plants, such as ship building yards, steel mills, etc., one or more double head sirens are used. Some are designed to give only a general alarm to notify the plant's fire corps, voluntary or paid, that there is a fire. Others give signals to indicate where the fire is located and then stop. Others automatically continue to repeat the signal until they are shut off. The number and kinds used vary with the conditions in the plants in which they operate. The Bethlehem Steel Works, for example, has sixteen double head sirens.

Large concerns in isolated locations and which have volunteer fire departments, prefer the large electric siren to give a general alarm, which not only serves as a warning of fire to the fire corps and employees, but also notifies the nearest municipal fire station of the fire. Where the siren serves this double purpose, it is located outside of the plant.

Industries of average size use either the single horn siren or the small type, shown alongside of the larger one. The single horn siren which emits a much louder sound than the Type "A", as we term it, is preferred where there is much noise caused by the operation of the machinery such as punch presses or hammering devices. In such plants, a signal system is generally devised so as to indicate the location of the fire. The small type is used inside of smaller plants and in larger places where there is little noise, such as warehouses, storage plants, schools and offices where these are located within municipal fire limits. Concerns located outside of the municipal fire limits invariably use the double-horn siren. Besides acting as a warning of fire which is distinctive and which cannot fail to be heard, they are often used as quitting and starting signals.

SHOWING THE TWO STYLES OF SIRENS.

## THE EFFECT OF NICKEL AND COBALT ON CAST IRON

Various researches have been made from time to time on the additions of special elements to cast irons, with a view of improving their properties. In a recent issue of "Stahl und Eisen," Bauer and Piwowarsky describe some experiments which they have carried out on nickel and cobalt additions to cast iron. The raw material used was a Swedish charcoal pig iron, containing 3.90 per cent. total carbon, 2.80 per cent. graphite, 0.048 per cent. phosphorus, 0.18 per cent. manganese and 0.69 per cent. silicon. After melting in crucibles, suitable additions of nickel were made and the metal poured into dry sand moulds. Suitable samples were taken for analysis, tensile tests, impact tests, compression and hardness tests. From the tables given the addition of 1 per cent. nickel shows the best figures. The increase in bending strength as compared with the original cast iron is approximately 30 per cent., the compressive strength is increased 30 per cent., and the tensile strength by 18 per cent. The following are the mean figures for an addition of about 1 per cent. of nickel: Total carbon, 3.89 per cent.; graphite, 2.85 per cent.; nickel, 0.87 per cent. Bending strength, 31.3 kg. per sq. mm.; deflection, 6.8 mm.; tensile, 12.5 kg. per sq. mm.; compressive strength, 74.75 kg. per sq. mm.; Brinell hardness, 171. For the manufacture of high quality castings for machine parts, gear wheels, etc., the addition of up to 1.2 per cent. of nickel is recommended. The results obtained by cobalt additions show that its effect is opposite to that of nickel, and the authors consider that there is no possibility of using cobalt for improving the qualities of cast iron.—Engineering Review.

## SHALLOW WATER VESSELS.

The problem of finding a satisfactory means of propelling craft in very shallow waters is one which is of great practical interest in many parts of the world. A British engineer who has given special attention to it has evolved a method of jet propulsion which gives very satisfactory results. A centrifugal pump fitted on an upright spindle draws water in at the centre and discharges it by two mouths at the sides. When the jets are thrown aft, the boat moves forward; and since the pump can be turned round it affords a means of steering as well as propelling the boat. Should the boat run aground, the pump can be used to squirt water on the mud or sand, so as to gradually wash it away and enable the boat to get clear. A weed cutter is provided at the mouth of the pump to remove any vegetable growths which may collect there. Although this method of propulsion is not so efficient as the ordinary screw, it is much better adapted to the navigation of shallow weed-clogged waterways. Tests which have been carried out on about two hundred miles of derelict waterways have proved the practical value of the invention.

# Have You Tried This Contest Yet? If not--- Do so Now

Below will be found twelve references to advertisements in this number. To the sender of the first correct set of answers to these we will forward one of these scales.
To win one is not difficult, and at the same time you will add to your store of knowledge. Read the details given below.

The scale is 6 in. long and is made from finest quality steel. One side is marked in 32nds, the other side in 64ths. A table of decimal equivalents is also stamped on one side, and a table of tap drill sizes on the reverse side. This scale is well worth securing.

## What You Have to Do

We publish every week a number of interesting facts or statements selected from the advertising pages for that week. The selections for this issue are given below. Read these through, then turn to the advertising section and see if you can pick out the advertisements to which they refer. The work is interesting, it will train your powers of perception and of memory, it costs you nothing, it will make you better acquainted with the various lines of machinery and tools in the market, and with perseverance you are bound to win one of these useful scales as a prize.

Several contestants submitted correct answers to all the questions in June 2nd issue. Following are the names of those who submitted correct lists. J. B. Smith, Canadian Link Belt Co., Toronto; J. H. Wood, St. Catharines; C. Newman, St. Catharines; B. Back and F. E. Regan, both with the P. B. Yates Machine Co., Hamilton. In the elimination test, J. B. Smith was the name picked as winner. We still receive letters stating that correct lists were forwarded which we don't acknowledge. Such lists never reach us, otherwise we would mention them.

**CONTEST FOR JUNE 23RD ISSUE**

**Contestants are required to write us, stating to which advertisements we refer in this number.**

1—Something that uses a 10 H.P. Motor
2—A very essential quality in a W——?
3—How to waste—or save.
4—A small——? for a big job.
5—Something that means lower costs.
6—What to do if you require special machinery
7—A development of 74 years' policy.
8—Two opposites handled with smoothness and accuracy.
9—Something used for all kinds of general D——?
10—A case where space was too small.
11—A product that set a new standard.
12—Something dated Sept., 1920, which is most important.

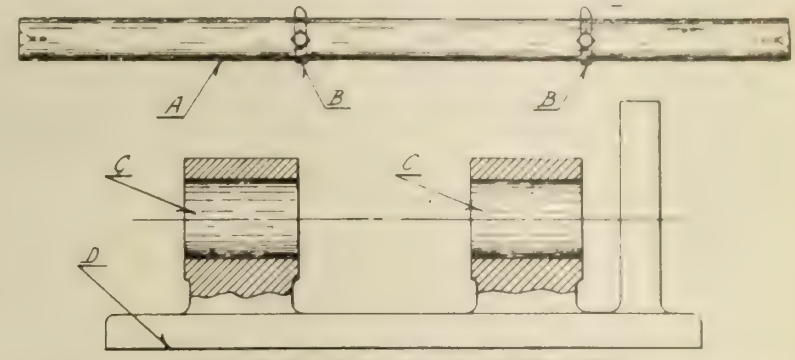
**These are Correct Answers for List from June 2nd Issue:**

1—Hamilton Gear & Machine Co.
2—National Electro Products, Ltd.
3—The Canada Metal Co., Ltd.
4—Canadian Steel Foundries, Ltd.
5—Canadian Blower & Forge Co., Ltd.
6—La Salle Tool Co.
7—Pilot Steel & Tool Co., Ltd.
8—Nicholson File Co.
9—Hull Iron and Steel Foundries, Ltd.
10—Parmenter & Bullock Co., Ltd.
11—Dominion Steel Products Co., Ltd.
12—Hamilton Engineering Co., Ltd.

## Closing Date for This Contest is July 14th

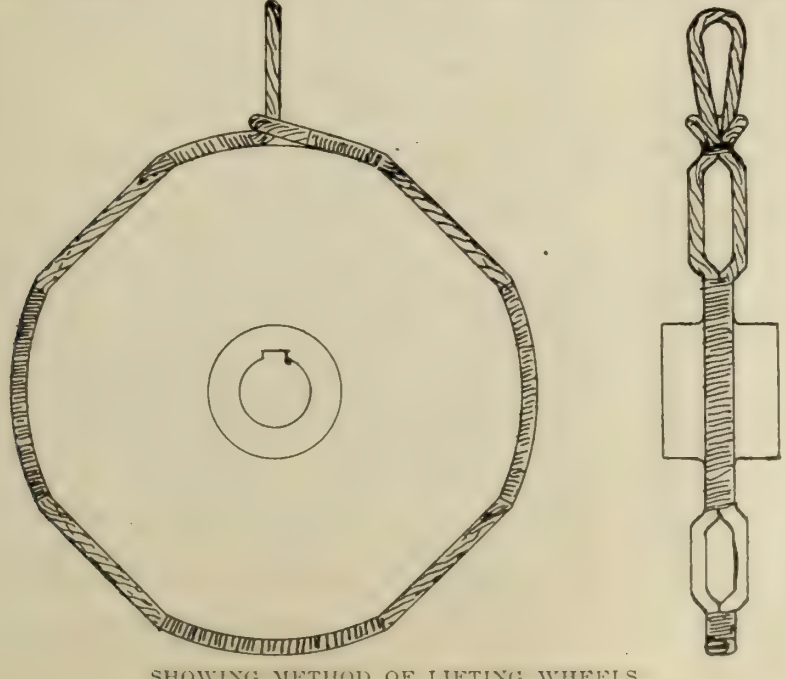
# WHAT OUR READERS THINK AND DO

### LIFTING DISC WHEELS



By JOHN S. WATTS

To get a hitch on a plain disc wheel, such as an idler sprocket or crank disc, with a narrow rim, that will be safe under all circumstances, and will not interfere with the placing of the wheel on its shaft, is a problem that is sometimes met with, and the proper and safe way to do this is not as well known as it ought to be.



The sketch accompanying this article shows how the rope should be laid, that is by tying the two parts of the rope sling together at intervals, and letting the wheel rim slip in between the two ropes between these intervals. When the wheel is heavy, the safe way is to tie the ropes together at about the spaces shown, by serving the double rope with heavy cord or marlin.

It is obvious that the sling will grip both sides of the rim of the wheel, holding it in what is practically a cradle, and that it is impossible for the wheel to get out of the sling while its weight is supported by the rope. The wheel when slung this way can be handled with perfect ease, as it will hang vertically, and can be slipped onto its shaft with facility.

When handling such parts out on the job, away from the cranes, the novice is apt to waste considerable time in skidding it around. If the wheel is lying flat on the ground, by placing a round stick or pipe in the bore, and wedging it there, the wheel can be easily tipped up vertically, because of the leverage of the pipe, and once having it in this position it can be rolled to its destination quite easily, even if of considerable weight, as the pipe furnishes a means of controllng its movements.

PLEASE SEND IN YOUR REPLIES PROMPTLY.

SHOWING METHOD OF LIFTING WHEELS.

### PARAFFIN ENGINE.

Several British engineering firms have been giving attention to the production of small robust petrol or paraffin engines specially adapted for agricultural use or in other situations where expert supervision is not available. In one of the latest products of this class, separate cooling tanks (which take up a great deal of space and make the equipment much less portable) are eliminated, and the cooling of the cylinder is affected by means of the water in an extension of the cylinder jacket. No pump, piping, radiator, or other complication is used. A three horsepower engine of this type weighs 382 lbs., and runs at 600 revolutions per minute. It operates equally well on petrol or paraffin and is built to give reliable service under the most exacting conditions.

### BORING WORK QUERY.

(By R. James).

In using the bar A for boring out the holes C C in the piece shown in the sketch, what would be the result if the lathe centers were out of alignment? Wold the holes be parallel or tapered? Would the holes be parallel or tapered? other? The work is secured to lathe saddle, and the bar held between the centers.

### BORING TOOL SET

A boring tool set with several distinct features has been developed by the Cascade Tool Company of Cohoes, N.Y. The sets consist of a holder, clamp bolt, two eccentric spring sleeves and three boring bars, each fitted with high speed steel bits. The tool holder is made in two pieces permitting it to be swung to any desired angle, and the tool may be used for turning the outside of work when same could not be done with the ordinary boring tool.

### VANADIUM STEEL.

"Vanadium in War and Peace" is the title of an illustrated booklet issued by the Vanadium Corporation of America, New York. It is introduced with a short history of the metal and the ore, particularly the supply of the latter. Then follows a large array of short illustrated articles on the various applications of vanadium steels in aircraft, automobiles, artillery, locomotives, etc. Charts of the physical properties of vanadium steel at different draw-back temperatures are included as well as an alphabetical list of given applications of vanadium steel.

## Old Machinery Lowers Profits

WRITING on the subject of "Getting Back to Economical Manufacturing," W. R. Basset, of Miller, Franklin, Basset & Co., claims in a recent issue of "Factory" that the scrapping of antiquated machinery often saves money. He writes as follows:—

The amount of supplies to be used for a given job can often be standardized just as the amount of productive material to be used is predetermined.

This method has been worked out by many different industries and for many operations. A careful study should, of course, be made, and if it is possible to standardize, it is well to do so. At the end of the month, by comparing the total amount of supplies used with the total number of units produced, a prompt check is had as to whether or not the standard methods are being lived up to. It is often possible to offer incentives to operators to meet the standard.

So much attention has been given in recent years to efficient methods of handling materials that it does not seem necessary to lay much stress upon that feature here. The development of industrial trucks and conveyors has been widespread, so that the proper equipment for nearly any condition can be readily chosen.

A word of warning would perhaps not be out of the way. That is, that an executive's enthusiasm for efficiency may here lead him into spending an undue amount of money for equipment. I have in mind an instance in which one man's time was given up to doing a certan bit of trucking. As it was considered in this plant to be inefficient to have a man doing a machine's work, a conveyor was installed which required not only a man to load the conveyor, but another at the other end to unload it, obviously a poor investment. Then, too, I have seen plants which although equipped with the most modern haulage devices, were so poorly laid out that their trucks were travelling from two to five times as far in a day as would have been necessary had the plant been rearranged so that sequential operations would have been closer together.

Another source of loss which is not uncommon is that of using antiquated machinery. I have in mind a plant which was using three old machine tools rather than spend the several thousand dollars which would have bought new ones. As a matter of fact, the management did not realize the losses that were occurring. A study of production, however, showed that these tools were turning out only about 75% as much as they should have, and that three or four times as much money was being spent for repairs to them as new tools would have required. When this condition was translated into dollars and cents, the new equipment was purchased and the old tools given a complete and thorough overhauling which put them into such condition that they could be used for other purposes without undue loss.

While at the present time few manufacturers are in a humor to replace old equipment with new, the savings which can be made are worthy of thought, for such savings continue year after year.

## The True Executive

IN speaking to the Civic Development and Advertising Council at the Chicago Association of Commerce, J. George Fredrick, president of the Business Bourse International, Incorporated, handed out a few hot liners of truths.

Among other things he said: "We have put on long pants—been boys in business, both domestic and export, long enough. We are guilty of criminal failure because we do not look facts in the face and anticipate situations, guilty of ineffective planning and of inflated ideas.

The traditional big boss who made all the decisions for the firm has been abandoned. The true executive is not a boss; he's a coordinator. He picks the right man for the right place and puts responsibility on him till he "cracks"—then he knows this man's capacity.

We have had vast resources to back us and easy sledding in their development. That is all passing. We are doing business on lower margins; we must handle finer adjustments, as Europe has done before us.

Sales methods must be trimmed and revised to meet such big forces as chain stores and cooperative societies. England has 9,000,000 cooperative buyers out of 40,000,000 people. This is coming to us. The public will not stand high prices. It wants to know why it at times costs five times as much to sell as to produce; a situation without justification.

Scientific purchasing compels the manufacturer to engineer his selling to meet the buyers' demands. Selling in the future must be accomplished by sincere cooperation between the sales department and the jobber and dealer.

Business success is based on these essentials,: men, information, policies. If we handle these properly we take the "hunch" out of business.

## Aerial Photography

SPEAKING on aerial photography, F. E. Haggvist, in Textile World, has the following to say:—

Before the world war aerial photography was practically unheard of. During the war its development was rapid because observers without cameras could not be depended upon to report with sufficient certainty to be of great material use.

Aerial photography opened up many new fields, among which is the photographing and mapping of industrial plants and grounds.

Photographs show truthfully all scrap piles, littered grounds, and poor arrangement, and when they are to be used for advertising or publicity work may be improved in appearance by retouching. Pictures are especially useful in the careful analysis of a plant for future planning and extensions.

Quite as important as the large aerial photograph is the mosaic picture or series of pictures, in which may be shown the complete plant, dams, canals, water supplies, railroads, streets, houses, and undeveloped property.

The use of aerial photographs saves expensive surveys. Sections to be studied may be printed and used for making notations, laying out work, or planning future development.

## Rules for Industry

CAN we make rules for industry? According to a recent article in Daily Financial America, we can, and here is how they present their claims:

The findings of the commission which has been studying the economic situation in Belgium might be considered with profit. Among the recommendations made by the commission are the following:

To market cheaply industry must be improved by the most modern technique, and the most up-to-date improved machinery. In organizing the industries, specialization and standardization needs must be taken into account, and the mechanism must be designed and adapted to meet these requirements. Industries and manufacturers are advised to combine for the economic handling of credits, and so on, through banks and export agencies, acting for the collective interests of all. Appeals should be made to agents of industry and well-informed workmen for increased production, and, in addition, methods of remuneration that will incite workers to produce more should be applied. To avoid conflicts with workers, committees of employees should be set up to control the internal or domestic mechanism of the industry.

By following these recommendations Belgian industry has already made notable strides toward recovery. The lesson may well be followed by industry in other countries.

## Important A. S. M. E. Papers

The recent convention of the American Society of Mechanical Engineers at Chicago, Ill., was a huge success, many papers of importance being presented. The section on machine shop practice met simultaneously with the fuel section, the presiding officer being F. O. Hoagland, vice-president and works manager Bilton Machine Tool Co., Bridgeport, Conn. Four of the papers presented had to do with the influence of the automobile on the machine tool industry and the fifth, entitled "Fundamentals of Interchangeable Manufacture," was presented by the author, C. B. Lord, works manager Advance Rumely Co., Battle Creek, Mich.

A paper on the influence of the automobile on the machine tool industry in general, written by F. K. Hendrickson, Reed-Prentiss Co., Worcester, Mass., was read by Forrest E. Cardullo, chief engineer C. A. Gray Co., Cincinnati. Luther D. Burlingame, industrial superintendent, Brown & Sharpe Mfg. Co., Providence, R. I., read a written discussion of Mr. Hendrickson's paper. Mr. Burlingame pointed out that the influence of the automobile industry was not only to be noted in the machine tools directly used in automobile production but also in the gauges and tool equipment required in the interests of accuracy and precision. He also mentioned grinding machinery as a type of equipment which had been developed rapidly under the impetus of the demands of the motor output. Without grinding machines, he said, it is doubtful whether the automobile industry would be commercially possible. He asserted that hardened gears, curved tooth and bevel gears and worm gear drives have all been brought out and developed because of the demands of the motor industry.

Sol Einstein, chief designer for the Cincinnati Milling Machine Co., read a written discussion. He pointed out how another automobile work influenced the design of milling machines and how it resulted in bringing out automatic feeds and intermittent feeds and returns on milling machines first developed by his company in 1910.

In commenting on Mr. Hendrickson's paper, J. A. Smith, general superintendent General Electric Co., Schenectady, N. Y., stated that there is an increasing demand for strength, power and speed in machine tools and for better quality and durability of the materials of which the machines are made. Precision and specialization in machine work brought to the fore by the automobile industry are possible greater degree in shops doing work involving little variety.

Mr. Smith laid particular emphasis upon lubrication, contending that machine tool builders are less up to date in matters of lubrication than in other particulars. It has been the experience of the General Electric Co., he said, that the majority of machine tool repairs are due to lack of lubrication. He attributed this to the fact that many oil holes are difficult to find and machine operators often forget to take care of the oiling. In a shop where duties are specialized he said it is not possible to induce workers to give the same attention to oiling that is given by the old-time all-round machinist. He asserted that machine tool designers should provide larger and more easily accessible holes and should reduce the number of the holes.

### The Machine of the Future.

Mr. Lord asserted that from a manufacturing standpoint specialized tools, in the sense that they can perform numerous operations, are not wanted. The machine of the future he asserted will not be a complex machine doing multiple operations, but a simple machine doing a multiplicity of one operation, or in other words getting out a maximum output of one kind of product. He asserted that too many feeds and speeds are objectionable because they provide too many ways of getting out of order.

In commenting on the subject of lubrication brought up by Mr. Smith, Mr. Cardullo asserted that the trouble lay in the fact that oiling has not been functionalized like other operations in a specialized shop. If a responsible employee were deputized to keep tools properly oiled, he remarked, there would be little further trouble along this line. Much of the present difficulty is due not alone to the failure to oil but to the use of oil of improper viscosity. He stated that machine tool designers cannot build machine tools with a tight housing so that they may be flushed with oil like an automobile, but that certain parts by the very nature of things must be left exposed.

### The Question of Painting.

Mr. Hoagland brought up the matter of painting machine tools, stating that in the textile industry all machines are painted green, probably because that color is restful for the eye. Mr. Smith stated that to his mind gray would be the best color for machine tools, as it is an excellent reflector of light and would be kept clean. He mentioned, however, that unless machine tool builders adopted a uniform color other than the black now in use, the effect would be anything but desirable in a large shop. In a small shop, of course, all of the machines could be repainted to one color by the buyer.

Mr. Cardullo did not take kindly to the suggestion that an excess of weight in the machine tool is a desirable feature. He stated that each machine is in itself an engineering study and that only enough pig iron should be used for the castings to give the machine durability and sufficient rigidity to withstand vibration from unbalanced work.

Henry J. Eberhart, secretary Newark Gear Cutting Machine Co., Newark, N. J., read a paper on the influence of the automobile on gear cutting and gear cutting machinery. In it he traced the history of the development of gear cutting and pointed out how remarkably accurate were the forecasts of pioneers in this work. In commenting on the paper Mr. Cardullo stated that although theoretically gears of 20 deg. angle and over should operate as quietly as gears of 15 deg. angle and less, that was actually not the case.

The relation of the power press and dies to the automobile industry, was the subject of a paper presented by Neal W. Dorman, machine designer, Toledo Machine & Tool Co., in the absence of the author, Henry J. Hinde, president and general manager of the company. Erwin E. Wood, sales manager Jones & Lamson Machine Co., Springfield, Vt., read a paper on the influence of the automobile on lathe practice in the absence of the author, Ralph E. Flanders, manager of that company. In speaking informally on the subject of his paper on the fundamentals of interchangeable manufacture, Chester B. Lord stated that engineers often fixed small tolerances when actual practice did not demand it and that greater accuracy was possible when operations were simplified and the tolerances were small than when wider tolerances were provided for and a multiplicity of operations was attempted on one machine. Subdivision of work, he asserted, is a function of accuracy.

### Machine-Tool Standardization.

Following the reading of a letter from Mr. DuBrul, manager of the National Machine Tool Builders' Association, asking for the standardization of the commoner machine-tool parts as well as the placing of a limit on the number of sizes of different types of tool, a motion was passed asking that the secretary recommend to the council that a committee on standardization of machine tools be appointed. In his letter Mr. DuBrul pointed out that there are 72 different sizes of upright drills, of which 28 are made by one manufacturer whereas he proposes 8 different sizes to meet the demands of the users. In the discussion it was brought out by various members that lathe spindle tapers and lathe spindle noses were among those things which might well be standardized.

---

## Good Times Are Actually Here

THERE was never more opportunity than now. One has only to look to see it." Elbert H. Gary, chairman of the board, United States Steel Corporation, makes this statement in a recent issue in "System," where an article termed "The Better Way to Plan Ahead" appears.

Among other important matters he touches upon the question of prices, and says as follows:—

The price equation is a very delicate one and I think that reason is a safer guide than emotion in approaching this entire subject of prices. It does not do either to raise or to cut prices without thought of the consequences—without thought as to what will be the effect on to-morrow's business.

The fair price is that which yields to an investment fair return for capital under efficient management—which pays adequately for the service that it renders. The same rule holds with labor. In the end that is all any of us can be paid because we are paid only out of what we produce. We cannot alter the equation—although we can try to forget it for awhile. Therefore I hold that:

(a) The depression has been wholly salutary in that it has served to bring us back to the fundamentals of business. Without the practice of the fundamentals no progress is possible.

(b) Unreasonably high prices will serve only to hold back the natural growth of the country, for they disturb the balance between the sections of society and curtail the strongest purchasing power.

(c) Unreasonably low prices will equally retard growth—for we shall have no surplus to grow on.

(d) Fair prices are an indication of prosperity. Unreasonaby high prices indicate that the period is nearing an end. The safe price is the one that returns a fair measure for work but returns nothing without work—whether the work be individual or corporate.

# DEVELOPMENTS IN SHOP EQUIPMENT

### WEB THINNING ATTACHMENT.

Herbert Hunt & Sons, Old Trafford, Manchester, have introduced a new feature to their patent twist drill sharpening machine. This attachment is to be used for sharpening and thinning the web of a drill without removing it from the original setting.

When the drill is in position for grinding the cutting lips, it is constantly rotated, and by a cam motion which repeats itself twice per revolution, the correct clearance is given to the cutting edges.

In the thinning of web position, the drill remains stationary, and the grinding wheel is situated in order to grind across the lips completing the grinding on one side before dividing round a half turn and grinding the other side. The drill remains in the chuck and centralizing bush for both operations. It is only necessary to move the cross slide from one position to the other and the drill will then engage with the correct grinding wheel; no re-setting whatever is required.

The arrangement for thinning is of simple construction, the auxiliary wheel being driven from the main spindle by means of friction rollers which can be engaged or disengaged at will. The thinning arrangement mounted on ball bearings swings round the main spindle, and can be adjusted for height by means of a knurled screw which comes in contact with stop. Behind the chuck which holds the shank of the drill is fitted a notch plate and latch for dividing for two positions 180 degrees apart. As the drill is originally set with the lip in a horizontal position whilst the latch is engaged in one of the notches an absolutely accurate means of equal depth of grinding is easily obtained for both sides of the drill.

### CUT-OFF SAW TABLE.

The Oliver Machinery Co., Grand Rapids, Mich., have placed on the market a new swing cut-off saw table. It is 16 ft. long, 19½ inches wide, and 30 inches high, being designed for use with the overhead swing cut-off saws. The top is made of kiln dried rock maple with angle iron girths and one piece cast iron leg sof rigid design.

The table is composed of two parts or sections. On the rear of the right hand section is mounted the scale rail, the scale rail being graduated in eighth inches from 0 inches to 96 inches, plainly marked and accurate. On the left hand section is mounted a patent automatic swing cut-off saw gauge which comprises a square rod graduated in eighth inches from 0 inches to 96 inches, plainly marked and accurate. Four automatic malleable iron stops, one center and two end rod holders are mounted in place. This automatic saw gauge is said to be a wonderful time saver where any number of parts are to be cut off to the same length. After the gauge is once set it is thereafter unnecessary to measure any board which is to be cut off to the ength designated by the stop. Rollers are inserted in both sections of the table in every other opening the full length of the table. A dust chute is fastened between the two sections of the table, having 6 inch diameter pipe opening connecting to exhaust system.

### INDEXING TABLE.

An indexing table for use in connection with machine tools has been brought out by the Industrial Engineering Company of Detroit, Mich. Two sizes are made, the tables being 10 and 16 inches in diameter. The table may be moved through 180 degrees and clamped in position by one movement of the operating handle. The bearings are of large diameter and the low height of the fixture makes it a very rigid device. The control of the indexing is by means of a special lock which automatically takes care of its own wear. Positive alignment of jigs or fixtures is tained by means of a slot across table. T-slots are provided for clan ing purposes.

### IMPROVED PNEUMATIC RIVETER

A Sheffield firm has introduced a ne type of snap for pneumatic riveters, th is said to be an improvement over fo mer snaps which have a tendency break. The weakness in the new sty is claimed to be eliminated.

The head of the snap shapes in grad ally towards the shank and a loos washer fits over the shaped part, thu providing the square shoulder require to fit the hammer head This loos washer also takes the rebound of th hammer but it does not bear any of th force of the blow. The net effect is t give much greater strength to the snap Careful tests have been carried out o structural and shipbuilding work, show ing that the improved head stands up t its work much better than the usua form. The material used is a specially tough steel intended to resist crystal lization due to repeated shock.

## The Careless Employee

CARELESSNESS, unfortunately, is a rather common commodity in any industrial plant. We are sure to find some fellow that leaves a file in his drawer, sticking long end out, because it would have taken a second or so longer to open the drawer up correctly.

Then there is the worker who piles castings loosely and carelessly, not because he wants them to fall on someone's foot, as they usually do, but simply because he has learned the careless habit. And so it goes.

The latest example of carelessness that has come to our attention has been reported by C. W. Graham of the Buntin Gillies Co., Ltd., Hamilton. In this case the carelessness of one of the employees in leaving a tap running amounted to between $2,000 and $3,000.

Late in the evening, water was seen emerging from the front door of this concern. Upon investigation, it was found that a tap on the third floor had been left unchecked. Only a water tap—yes—but how easy it would have been to turn it off correctly.

## A Regrettable Incident

"ON Account of Irregularities," thirteen students have had their examination results canceled this year at the University of Toronto. Eight of these have suffered expulsion.

What does this word "Irregularities" mean? Unfortunately, when boiled down to hard and cold facts, it means that four students have been expelled for impersonation; one student has been expelled because of his expulsion from the college of the university in which he was registered; three students have been expelled because they secured a copy of the paper on which they should have written and on the excuse of writing on another subject left the university halls, completed the writing of the paper elsewhere, and in the confusion at the close of the period of examination submitted their answers to the presiding officer.

"In the case of the expelled students the examinations of this present year are canceled, and they are debarred from registration in any faculty or department of the University of Toronto.

"Another student has had his May results canceled because of copying, and has been refused registration for the session 1921-1922 and 1922-1923, and admission to any examination earlier than May, 1923.

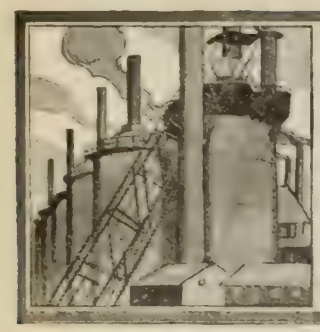
"In the case of another student, who denied any irregularity until the evidence against him was so strong that confesson had to be made, it has been decided to cancel the examination results, to debar him from registration in any faculty or department of the university for the session 1921-1922, and to permit him to regiser in the session 1922-1923, but without examination until May, 1923.

"Still another student, who when charged at once admitted his guilt, has had his results canceled, has been refused registration in any faculty or department of the university for the session 1921-1922, and is debarred from examinations earlier than September, 1922.

"Two other students have had their results for the year canceled on account of copying; they at once admitted their guilt and are refused registration for the session 1921-1922, but may come up for examination in May, 1922

"Irregularities" is indeed a mild word to use in such a case. Dozens of appropriate titles rise to our mind, "Downright Deceit" and "Ungentlemanly Conduct" being two of the mildest we can think of. When we look back on the days when a man entering college had a code of honor that prevented "cribbing" in any shape or form, we cannot help but think that times have changed for the worse.

If this is so, and we believe it is, steps should be taken at once to remedy the trouble. We have faith enough in the majority of our college students to state that this untortunate occurrence is more a regrettable incident, than a common practice, yet no stone should be left unturned in the effort to stamp out the new-found evil. Temptation is a hard thing to overcome, especially when examinations come round, and those in charge should see to it that such an incident can never occur again.



There is no short cut to success. The road to that desired of all goals, "Success," is beset with many an obstacle. There is only one real way to overcome these difficulties, and that is by "Good Hard Work."

## The Art of Knowing How

THERE is a story told, and a true one, of an express train running between Philadelphia and New York, that came to a sudden stop on an extremely hot day last summer. Accordingly to the tale, the passengers first joked, then grumbled, and finally grew impatient.

A man, white-haired, but youthful in motion, climbed down from a chair car and marched up to the engine, which was the center of a ring of passengers. "What's wrong?" he asked. In effect, the engineer said that the engine had quit and he didn't know what the several things were that were the matter with it. The big man peeled off his coat and waistcoat and rolled up his shirt sleeves. Then he sort of disappeared in the interior of the unwilling engine and the ring of watching passengers grew. Half an hour later he emerged with a smudged face and grimy hands and said, "She's all right now," put coat and waistcoat over his arm and walked back to his chair car, wiping his hands on a handful of waste he'd picked up in the cab.

Doubtful, the engineer tried the engine out, and lo—she worked. Later on it was discovered that the friend in need was none other than Samuel Matthews Vauclair, president of the Baldwin Locomotive Works.

# MARKET DEVELOPMENTS

THE situation in the steel business shows no signs of improvement, and it is possible that the immediate future will show a further decline. The one hopeful sign is that there seems to be a movement in the direction of liquidating stocks on hand, which though slow at present, may assume greater proportions as the harvest season comes along.

The independent mills are running at about 15% capacity, while the Steel Corporation has increased from 30% a week ago to about 35% at present. The increase in the Corporation's output is attributed to the fact that all buying is for prompt shipment, and the Corporation having always got a mill running somewhere, can give delivery more satisfactorily than the independents. There is some chance of more mills being shut down altogether next month. It is pointed out that this is no remarkable thing, but on the other hand it was at one time a common practice, which has been dropped under the greater volume of production of recent years.

Steel prices remain the same, there being no temptation to reduce them under present market conditions. While steel buyers are undoubtedly waiting for a reduction before doing any extensive buying, sellers figure that there is nothing to be gained by making reductions on small amounts, but rather wait till a reduction would induce a large volume of buying. With such a condition their production costs would decline, and the cut would not mean so much to them as it would at present.

Pig iron of the basic grade has shown a little reduction from $21.50 to $21 Valley, while Bessemer remains at $23 and foundry $22.50. These prices would probably be shaded on a large contract.

## BUILDING TRADES LABOR SLOW IN STRIKING AN AVERAGE

THE situation in the steel business shows no signs of improvement, and it is possible that the immediate future will show a further decline. The one hopeful sign is that there seems to be a movement in the direction of liquidating stocks on hand, which though slow at present, may assume greater proportions as the harvest season comes along.

The independent mills are running at about 15% capacity, while the Steel Corporation has increased from 30% a week ago to about 35% at present. The increase in the Corporation's output is attributed to the fact that all buying is for prompt shipment, and the Corporation having always got a mill running somewhere, can give delivery more satisfactorily than the independents. There is some chance of more mills being shut down altogether next month. It is pointed out that this is no remarkable thing, but on the other hand it was at one time a common practice, which has been dropped under the greater volume of production of recent years.

Steel prices remain the same, there being no temptation to reduce them under present market conditions. While steel buyers are undoubtedly waiting for a reduction before doing any extensive buying, sellers figure that there is nothing to be gained by making reduction on small amounts, but rather wait till a reduction would induce a large volume of buying. With such a condition their production costs would decline, and the cut would not mean so much to them as it would at present.

Pig iron of the basic grade has shown a little reduction from $21.50 to $21 valley, while Bessemer remains at $23 and foundry $22.50. These prices would probably be shaded on a large contract.

PITTSBURGH, June 23.—Undoubtedly progress is being made in the liquidation that must precede a recovery in the demand for steel. There are stocks of steel in the hands of jobbers and of manufacturing consumers that must be worked off, and still larger stocks of finished wares, such as agricultural implements, hardware, tools, cutlery, machinery, etc., that must be distributed. Steel manufacturers express conviction that even now there is some liquidation in these things, and they expect the liquidation to grow more rapid within a few weeks. In particular they think the farmers will become buyers again when they begin receiving payments on their crops.

According to the common analysis of the situation, these things must work out first, before there is any increase in demand upon the steel mills. There must also be a revival in building. In that direction conditions are probably improving, but certainly quite slowly. Building trades labor, striking an average of the whole country, is very slow in accepting readjustments, by way of wage reductions and greater performance.

The actual volume of specifications and orders received by the steel mills has decreased farther, much as might be expected, and if for no other reason on account of the season of the year, there is no likelihood of any increase in the next few weeks. The inflow of business probably averages between 15 and 20 per cent. of mill capacity and it may be still less in July. A further decline in production is therefore to be expected.

### Operations.

Current estimates are that the independent steel mills are operating at about 15 per cent. of capacity, against close to 20 per cent. say a fortnight ago. The Steel Corporation's operations are up to 35 per cent., having dropped to 30 per cent. a week ago. Precisely what has occurred to cause these changes is not known definitely, but a reasonable theory seems to be that on account of nearly all buying being for very prompt shipment the Steel Corporation has a decided advantage over many if not the majority of the independents. It is a case of "to him that hath shall be given," for the Steel Corporation nearly always has a mill running on which it can immediately schedule a specification received, while with the independents, some small mills have been closed entirely for months, and some have been running intermittently, say one week out of each three, and others while having some sort of an operation each week, taking the plant as a whole, have entire departments closed at times. Then, too, there are the Steel Corporation contracts, amounting to 5,482,487 tons at the beginning of this month, while the independents have little contract tonnage on books.

At 15 per cent. for the independents and 35 per cent. for the Steel Corporation, the average operation of the steel industry as a whole would be between 23 and 24 per cent., against about 23 per cent. a week ago, representing in general no material change for two or three weeks. Nevertheless the probability is that the rate of operation will go below 20 per cent. in July, a recovery coming in August.

One large independent mill has been closed tight. Previously it was only small mills that were closing completely, but by the beginning of July it is probable that several large plants will be closed entirely, not because they have no orders at all, but because operating plants at such very light rates is extremely expensive. It is not a matter of fixed charges, since they go right on when a plant is closed, but of high labor cost, for the number of workmen requisite does not decrease in full keeping with reduction in output. It is no remarkable thing for mills to close entirely at this season. Years ago that was a common practice but in recent years the practice died out.

### Steel Prices.

Inquiry is so very light that there is little temptation to sellers to shade prices. Perhaps they would not in any event, but the practical point is that the opportunity is lacking. Every mill knows by contact with its customers that orders would not be increased by reducing prices. The customers do not want to buy more than they are buying, and have no occasion to do so. They can fill their orders out of stock, or by their present production, and as to buying ahead, they can get shipment in most cases in two or three days after filing a specification or order and there is no indication that this condition will disappear. When there is a case of a mill not being able to fill an order promptly it is because the mill is idle, not because it is already full of business.

Ten days ago there were reports of shading in sheet prices by $2 or $3 a ton by several sellers. Now it appears that if these sellers were shading they have withdrawn the cut prices. At any rate, it does not appear that in general sheets can be bought at less than the regular or "April" prices. Heavy gauge blue annealed sheets are an exception as they frequently are, since from some mills they can be bought on the plate schedule..

Evidently practically all buyers of steel expect lower prices at some time, and before they buy to any extent. Sellers make no particular effort to combat this view. They admit the probability that prices will be lower, but they want to see a prospect of more business before they make regular reductions. No doubt their philosophy is that a well timed reduction would encourage buyers to take hold, while if reductions were made now they would simply fall flat. The mills would be giving something away for nothing, and it seems much better to save the reductions for a time when they will count. On account of light operation, most mills are probably having losses as it is and increased losses would only be invited if an eventual compensation were promised. If larger operation should result, then the production cost would decline.

### Coke and Pig Iron.

Two small contracts for Connellsville furnace coke have been closed, by the Colonial Iron Comany, Riddlesburg, Pa., and the Empire Steel & Iron Company, the Empire Steel & Iron Company, Catasauqua, Pa., respectively. Each is for about 7,000 tons a month, one being for July, August and September delivery at $3 per net ton at ovens, the other being for delivery to about December 1, at $3.15. In this price divergence the coke market runs according to its traditions, for as a rule coke has been worth more in winter. The prices are the lowest since the summer of 1916. In single carload lots standard furnace coke for spot shipment has sold at $3.10 to the consumer, $3.25 having been the minimum until quite recently. Foundry coke is easier at $4.50 to $5 for spot, according to brand.

Basic pig iron has slid off from $21.50 to $21, valley. Bessemer remains quotable at $23 and foundry at $22.50, but an inquiry of any size would probably develop concessions in the case of each grade.

---

The General Accident Assurance Co. of Canada, Ltd., Continental Life Bldg., are contemplating the erection of an eight or ten-storey office building.

## POINTS IN WEEK'S MARKETING NOTES

**Blast furnace operations are down to about 20 per cent. in the Pittsburgh, Valley and Wheeling districts. The amount of new business in pig iron, semi-finished steel and finished steel is also very low.**

**Consumers are not purchasing any more than they urgently need. Price changes, such as they have been, are unimportant. There is not even enough business to tempt makers to cut prices.**

**Consumption, in some districts at least, is equal to, or even ahead of production. This means that stocks are exceedingly low, and this fact is proven by the urgent mark when any orders are placed.**

**Pig iron, according to some dealers, is almost stagnant, and may drag along as it is for some months yet. Some look for lower prices, while others feel things have hit the bottom.**

**Practically nothing is being done on semi-finished steel, and sheet and tin plate mills are not running at more than 25 per cent. capacity. The Carnegie Steel Co. has no less than seven of its steel plants idle, and there is at present no indication of an increase in demand for billets or sheet bars.**

**The machine tool market is still very quiet, and dealers are none too optimistic about the future. The waiting policy is still in force.**

**There is no change for the better in nuts, bolts, or rivets, while some makers of hot rolled strips report a slight improvement in business. Several makers are even shading prices in an effort to get business.**

## TRADE RESIGNED TO PRESENT CONDITIONS

TORONTO:—The machine tool market is still very quiet, and dealers do not look very optimistically on the immediate future. Inquiries continue to be fair, but they are mostly in the nature of feeling out the market, to see if there is any chance of a price reduction. The general policy of waiting to see the turn of events on the part of buyers is still very much in evidence. What business is being done is in small tools such as sensitive drills, and the amount is very small.

The trade seems to be resigned to the prevailing conditions, and while not neglecting any openings, are prepared for a further period of slack business. The usual pious hopes of the effect of the harvest bettering conditions are expressed, but the situation is so world-wide, that local factors cannot have much of a permanent effect.

Steel warehousemen are in no better position than their fellows in the machine tool trade. While there are some enquiries, they are mostly for very small items, and even on these customers are inclined to haggle over prices. One dealer mentioned in this respect that he had filled an order this week for a piece of ⅜ bar, and this had to be delivered a matter of six miles out of town. There is a certain amount of business doing in black and galvanized sheets, but these lines are being ordered in very small quantities. Where bundles would be ordered formerly, orders for two or three, and in some cases single sheets are now received. On these small orders customers ring up two or three different dealers in order to get the best prices. Buyers of boiler tubes are also keeping strictly to the lowest limits of their requirements, and orders for tubes are sent in for quantities of two, three, or four at a time, eight being about the limit. The lack of construction work has of course, been keenly felt by steel warehouses, and there is not likely to be any large work going on until a reduction in building trade wages has been effected. While the production at the mills has been reported to be higher this week, steel warehousemen are inclined to think that the published figures are over, rather than under the actual amount.

The old material market shows no change, stocks in dealers' yards being about the same, and little buying being done.

## Pig Iron Markets

Following the long continued decline in pig iron prices, concessions are still being made. Prices on foundry irons are at least 50 cents lower in Cleveland and Chicago, and resale basic is a disturbing factor in the Pittsburgh district. Buffalo furnaces are competing actively and Chicago iron is being sold at low prices as far distant as Ohio.

Not a merchant blast furnace in the two Valleys or in the Pittsburgh district is in operation and all are likely to be idle for some months. Furnaces are shipping from stocks, the small orders for iron, they are getting. The only sale during the week of any size was one of 2,000 tons bought by a Shenango Valley open-hearth steel plant from a Youngstown steel interest at the reported price of $21 at furnace. A sale was made of 500 tons of No. 2 foundry for last quarter delivery at about $23 Valley furnace.

The ruling price in the Chicago district for No. 2 foundry and malleable ranges from $21 furnace for tonnage to $21.50 and $22 for carload lots. Even lower prices are being named on tonnages taken outside of this district where the competition of nearby furnaces must be met, and 500 tons of No. 2 foundry was sold in Ohio at $20 Chicago furnace. About 2,000 tons of resale foundry has been put on the market recently—no prices have been named on this iron, but offers have been solicited.

There is little doubt that the Buffalo market has reached the lowest ebb since the inception of the slump in business. Two factories have reported no sales and an announcement comes in from a producer that with the completion of orders on hand, its only furnace now in blast will be blown out. The price situation is responsible for the declaration —not fewer sales. A number of carload sales were made by a producer and in each instance the price was arranged mostly at a $23 base level.

A lot of 100 tons of Birmingham iron

was sold at Birmingham at $23.50 for silicon 2.75 to 3.25. This shows how the silicons operate on a $22.50 base. It is a differential of 50 cents for each of the higher silicons. Local iron melt is picking up owing to larger operations at stove and radiator plants.

Two sales of 500 tons each and another of 150 tons of foundry iron are the only sales of importance reported on the Philadelphia market during the week. Business for the week was mostly in carload lots. Eastern furnaces are quoting $24 for No. 2 plain, $25 for No. 2X and $26 for No. 1X, f.o.b. furnace.

The Cincinnati market has shown few developments in the past week. The Standard Sanitary Mfg. Co. bought 500 tons of Southern iron for prompt delivery to its Louisville, Ky., plant, and the National Cash Register Co. took 160 tons of Southern for its Dayton plant. The latter company is expected to close for an equal amount of Northern iron in a few days. Southern Ohio iron is still being quoted at $23, Ironton, for the base grade. Belfont stack at Ironton was blown out on Thursday. A local foundry has been asked to bid on castings for the New York harbor tunnel, involving approximately 150,000 tons of castings.

New York reports that a Connecticut consumer of foundry iron has offered to buy 5,000 tons if a substantial reduction in price were made and 5,000 tons more if the iron can be held for a satisfactory period in furnace yards for future delivery. This offer is one of many examples of the pressure that is being brought to bear to obtain lower prices and even the most optimistic sellers expect to see further concessions. 300 tons of Buffalo No. 2X was sold at a $22 base to a New York consumer. One consumer is offering $20 for iron and is confident of being able to buy at that price.

Cleveland reports that the Ford Motor Co. has sent out an inquiry for 60,000 tons of ore, but there seems to be some uncertainty whether this ore will be purchased. Many mining companies made another wage reduction on June 15th. This reduction brings wages back about to those that were placed in effect April 1st, 1918.

There is absolutely no business developing and practically no inquiry, in the St. Louis market, aside from the occasional sale of a car lot. The stove foundries seem likely to get along for some time on their yard stocks, the commercial foundries are operating on 25 per cent. or less capacity and generally the business is in a very dull state. The lowest price so far found here for No. 2 Southern is $22, Birmingham, but there is no business and therefore no competition to develop any definite price.

## Scrap Metal Markets

Consumers of scrap in the Pittsburgh and Valley districts are not operating their plants to more than 25 per cent. of capacity and are not interested at any price in offerings made by dealers, as they seem to have heavy stocks of scrap on hand. It is probable that on a firm offer, machine shop turnings could be bought at $7.50 per gross ton, delivered. Selected heavy steel scrap is being offered quite freely at $13 per gross ton, delivered, but there are no buyers. Prices are very largely nominal and there is little new business moving on which to base actual prices.

On the Chicago market consumers continue to buy sparingly, but such purchases as have been made indicate lower prices. 500 tons of heavy melting steel was bought at $11.50 per gross ton, 250 tons of No. 1 railroad wrought at $10 per net ton, 250 tons of No. 2 wrought at $9.75 and 200 tons of carwheels at $13.75 per gross ton. Offerings are not being absorbed as fast as a short time ago.

Boston reports machinery cast is easier in the absence of orders and greater competition among dealers. It is available at $17 to $17.50 delivered, even at points as far north as Biddeford, Me. Owing to the continued buying of stove plate by a railroad supply manufacturer, the prices are still firm.

The scrap market at Philadelphia has been in a nervous state during the past week, due to the depressed situation in the securities market. Prices remain easy and there has been no improvement in the demand.

At Cincinnati the market is stagnant and dealers are only buying to fill old contracts. Heavy melting steel is quoted at $10.00 to $11.00.

The volume of trade continues very light and prices have further declined on the Cleveland market. Cast iron borings, heavy melting steel, and mixed borings and turnings, are 50 cents a ton lower. Machine shop turnings have declined locally about $2 a ton, owing to the fact that dealers are not buying this grade for stock and the only market for it is in Brackenridge where this scrap is bringing $7.75. A Youngstown dealer is inquiring for 500 tons of shoveling turnings and 500 tons of compressed steel scrap, offering $9.25 for the former and $10 for the latter, delivered Wierton.

There is so little change in the market at St. Louis, that it is practically impossible to record any new feature. The softness of the market continues to prevent railroads and industries from offering any material and it is very doubtful if even the most daring of the dealers would make any purchase unless for actual needs on existing contracts.

## Trade Gossip

Plans are being prepared by Gascon and Parant, architects, 502 St. Catharine St. E., Montreal, for the construction of three-storey garage. The building will be 60x120, and of reinforced concrete construction.

The Canadian General Electric Co., 158 St. Antoine St., Montreal, have received the contract for electrical equipment and motors for asbestos and reducing mill costing $40,000 for Canada Asbestos and Chrome Co., Ltd.

The general contract for erecting garage costing $30,000 for Car Owners Garage Co., London, Ont., has been awarded to R. G. Wilson and Sons, 193 College St.

The Canadian Johns-Manville Co., Ltd., 450 St. James St., Montreal, has plans and will receive tenders, no closing date set, for general and steel contracts for two factories at Asbestos, Que.

W. T. Rawleigh, 55 Liberty St., Freeport, Ill., will erect a six-storey factory on Adelaide St., London, Ont., at a cost of $150,000.

H. Pelandeau, Ltd., 1211 Ontario St., Montreal, is in the market for complete planing mill equipment.

Dunker Bros., Louisa St., Kitchener Ont., are building a service station for Reinhart and Doerr, 192 King St., at a cost of $15,000.

W. Mahoney, 162 Anger St., Montreal, is in the market for two lathes and other machine-shop equipment.

D. W. Burnett, 1424 Richardson St Victoria, B.C., have received the general conract for installing battery of new boilers for sawmill at cost of $10,000 for the Alberni-Pacific Lumber Co Toronto Letter

The manufacture of lignite briquettes by the plant at Bienfait, Sask., will start in July, according to J. M. Leamy Manitoba Power Commissioner and a member of the Lignite Utilization Board. The chief engineer of the board, R. D. L. French, made the final inspection last week. A meeting of the board will be held soon in order to determine the price of the briquettes which will likely be about $11 per ton.

The Hydro-Electric Power Commission has arranged to get 1,000 kilowatts electric energy from the Campbellford plant. The accident at the Healey Falls Power Plant, makes it necessary for the Hydro to get all the power available so as to compensate in loss of power at the Falls. The City of Peterboro is 40 per cent. short of its normal supply of power.

The Palatine Mining and Development Company, which is rebuilding the blast furnace and opening up the Paulson Iron Mines near the international border, has asked the city to sell 200 acres of land at Bare Point for the construction of ore docks, to have a capacity of 500,000 tons. They also are planning to build 200 houses for workmen.

Mr. A. W. Rodger, chairman of the Southland Electric Power Board, Invercargill, New Zealand, who arrived in Toronto on June 16th from Niagara Falls, stated that "power companies in New Zealand are anxious that their orders for electrical machinery be supplied either by Canadian or British firms." Mr. Rodger stated that he would try and get contracts placed in Toronto and Hamilton for electrical machinery, insulators, and other products of electrical companies, that he would try and place contracts for the most up-to-date electrical cooking machinery within the next few days. The amount which he intends placing here and in Hamilton will amount to about a million pounds sterling.

Members of the Minto Coal Operators' Association, have been awarded contracts for the first coal from the Grand Lake coal areas of New Brunswick for use on the Canadian National Railways. The contracts call for delivery of 10,000 tons during the next six months and 5,000 more tons during a subsequent period. This announcement was made by John Henderson, chairman of the association on his return from Toronto.

Distinction has come to Montreal in the conferring by the University of Toronto of the honorary degree of Doctor of Science on two of the leading engineers of this city, Commissioner R. A. Ross of the Administrative Commission, and J. M. R. Fairbairn, chief engineer

f the C. P. R. Only four such degrees ave ever been conferred upon engineers, and three of them are held by lontreal men.

The Transportation Commission has laced an order with the United States teel Products Company, for street railay tracks and intersection material mounting to $400,000. Of this order about 75 per cent. is for steel rails. The order might have been placed in England had not the strike tied up transportation. Deliveries will begin in about two weeks and the entire order will be on hand by September 1st. Only one tender was received from a Canadian firm, and was for only a portion of the work, and the price about 12 per cent. higher and deliveries not so good.

## SALES TAX RESOLUTION AMENDED CERTAIN EXEMPTIONS ARE GRANTED

The recent resolution respecting ales tax has been amended. The bill, n its present form however, contains he same provision as last year, to the ffect that the purchaser shall be furished with a written invoice of any ales, which invoice shall state separtely the amount of such tax to at least he extent of 1½%, but such tax must ot be included in the manufacturers, roducers or wholesalers costs on which rofit is calculated; and the tax shall be ayable by the purchaser to the wholealer, producer or manufacturer at the ime of such sale. Here is the working f the provisions of the bill as passed y the House of Commons.

That in addition to the present duies of customs and excise there shall e imposed, levied and collected an exise tax of one and one-half per cent. n sales and deliveries by Canadian anufacturers or producers, and wholealers or jobbers, and a tax of two and ne-half per cent. on the duty paid alue of goods imported, but in respect f sales by manufacturers to retailers r consumers, including sales to his lajesty, whether in the right of His lajesty's Government of Canada or His lajesty's Government of any province of Canada for the purpose of re-sale, the excise tax payable on the duty paid value shall be three per cent. and on goods imported by retailers or consumers, including importations by His Majesty, whether in the right of His Majesty's Government of Canada or His Majesty's Government of any province of Canada for the purpose of re-sale, the excise tax payable on the duty paid value shall be four per cent.; that the purchaser shall be furnished with a written invoice of any sale, which invoice shall state separately the amount of such tax to at least the extent of one and one-half per cent., but such tax must not be included in the manufacturer's, producer's or wholesaler's costs on which profit is calculated; and the tax shall be payable by the purchaser to the wholesaler, producer or manufacturer at the time of such sale, and by the wholesaler, producer or manufacturer to His Majesty in accordance with such regulations as may be prescribed, and such wholesaler, producer or manufacturer shall be liable to a penalty not exceeding five hundred dollars, if such payments are not made, and in addition shall be liable to a penalty equal to double the amount of the excise duties unpaid; that the term "duty paid value" means the value of the article as it would be determined for the purpose of calculating an ad valorem duty upon the importation of same into Canada under the laws relating to the Customs and the Customs Tariff whether such article be in fact subject to ad valorem or other duty or not, and in addition the amount of the Customs duties, if any, payable thereon.

Provided that in respect of lumber an excise tax of two per cent. shall be imposed, levied and collected on sales and deliveries by the Canadian manufacturer and of three per cent. on importations and that no further excise tax shall be payable on re-sale.

There are various exemptions to this tax, but following are the items which will chiefly interest our readers: Ores of metals of all kinds; fuel of all kinds; gold and silver in ingots, blocks, bars, drops, sheets or plates unmanufactured, newspapers and quarterly, monthly and semi-monthly magazines, and weekly literary papers unbound; materials for use only in the construction, equipment and repair of ships; calcium carbide; electricity; gas manufactured from coal; and calcium carbide or oil for illuminating for heating purposes. The Governor-in-Council has power to add to this list if he deems it wise

It is further provided that the excise taxes specified in this section shall not be payable on goods exported, or on sales of goods made to the order of each individual customer by a business which sells exclusively by retail, under regulations by the Minister of Customs and Inland Revenue, who shall be sole judge as to the classification of a business and a draw back may be granted by ninety-nine per cent. of the said taxes paid on materials used, wrought into or attached to articles exported.

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

## CANADA'S TRADE BY COUNTRIES BRITAIN SECOND BEST CUSTOMER

THE trade returns for Canada for the year ending March 31st, 1921, are unusually interesting in that they indicate the new direction in which markets lie. Markets are the paramount question, for both in respect to raw and manufactured products the Dominion is producing a great deal more than can be consumed at home. The question of markets is the more interesting because the rate of exchange is militating so against exports to certain countries which formerly bought heavily of Canadian products, that other markets must, if possible, be found.

Total exports were $1,210,428,119, as compared with $1,286,658,709 for the year 1919-20. The decrease in the exports of domestic exports was not, however, so large, amounting to approximately $50,000,000. On the whole this is to be attributed to decline in prices more than to a decreased volume of shipments. Dealing only with exports of domestic produce, the United States was by far Canada's best customer last year, having taken $542,304,456 worth of commodities as compared with $464,028,183 for the preceding year, or approximately $78,000,000 more than in 1919-20.

The United Kingdom was Canada's second best customer, having taken $312,842,921 worth last year as against $489,152,921 in 1919-20, and $540,750,977 in 1918-19. During the last three years, while exports to the United States have increased from $454,873,170 to $542,304,456, those to the United Kingdom have decreased from $540,750,977 to $312,842,921.

**Trade With the Empire.**

The British Empire took last year a much less volume of commodities than it did during the preceding year. The figures were $403,470,602 in 1920-21 and $561,788,003 in 1919-20. This is explained chiefly by the decline in exports to the United Kingdom. During the year, exports to Australia increased by $6,750,000; to British Guiana by $585,000; to British South Africa, $8,000,000; to the British West Indies, $2,161,000; to Hong Kong, $657,000; to Newfoundland, $520,000; to New Zealand, $4,900,000. To other portions of the British Empire, there was a falling off to the extent of $3,000,000.

Turning to other countries, exports to Italy increased by nearly $41,000,000, to the Netherlands by $15,000,000; to the Argentine by $2,000,000; to other countries by $5,750,000. On the other hand, there were some notable decreases. Exports to France fell from $61,108,000 to $27,248,000; to Greece from $29,588,000 to $20,834,000; to Japan from $7,732,000 to $6,414,000.

Coming to imports, those from the United States increased by $55,516,112; from the United Kingdom by $87,148,000; from British Guiana by $1,676,000; from British South Africa by $690,000; from the British West Indies by $2,769,000; from Newfoundland by $640,000; from New Zealand by nearly $800,000; from Belgium by $3,750,000; from China by $683,000; from Cuba by $13,000,000; from France by $8,376,000; from Italy by $750,000; from the Netherlands by $2,000,000. Imports from the British East Indies declined to the extent of $2,000,000; Argentine by $1,000,000 and Japan by $1,578,000.

**Imports From British Empire.**

In the year just closed, Canada imported from the British Empire $265,877,691 of commodities out of a total of $1,240,125,056 from all countries; in the year 1919-20, the amount was $174,351,659 out of a total of $1,064,000; from China by $683,000; from 528,123; in 1918-19, it was $123,671,540 out of a total of $919,711,705. In other words, whereas in 1918-19, 13 per cent. of Canada's imports were drawn from the British Empire, last year the percentage was 20. At present it seems improbable that this percentage will be maintained. The marked increase during the year just closed was due to heavy buying in Britain during part of the year, which has since fallen off. The extent of the decline is to be seen in the trade returns for March, when the imports from the United Kingdom were $16,373,874, as compared with $25,460,316 for the preceding March.

Among the imports, iron and steel easily led with $208,288,669, cotton being next with $99,816,594. Then followed sugar and molasses, $86,070,230; bituminous coal, $72,239,952; wool, $67,017,640; anthracite coal, $39,058,148; silk, $29,720,792; vehicles, $27,694,577; wood, $30,237,528; chemicals, $24,621,000; and breadstuffs, $21,014,801.

**Country's Trade Widening.**

On the whole, the returns show that the basis of the country's trade is widening. It is true that last year approximately two-thirds of its total value was with the United States; but on the other hand, the proportion of trade with foreign countries generally increased. While the volume of trade generally with the Mother Country has declined, still more is being done with the other portions of the Empire. The premium on American funds has strongly stimulated commercial intercourse with the United States, and as the premium will undoubtedly continue for some time, it is reasonable to conclude that, in spite of the temporary obstacles, the volume of trade between the two countries will continue to be large. The indications at present are that the value of imports from the United States will appreciably decline during the current year, that process now being well under way.

## A GOOD IDEA

Can you imagine a Milling Machine as part of office equipment? It hardly sounds feasible, and yet the Ford-Smith Machine Co., Ltd., Hamilton, Canada, find that the placing of a miller in their office is mighty good business.

This concern, who manufacture a full line of milling machines, both plain and universal, decided it would be good policy to bring one of their machines right into the main office, so a suitable place was prepared; a universal miller was brought in from the machine shop, and there it stands. Anyone interested can inspect it to their hearts content, and in many cases the very fact of its being there, has caused favorable comment.

## TENDERS ASKED

It is announced that J. A. C. Cameron, master-in-chambers, at Osgoode Hall, will receive tenders for the sale of the assets of the Dominion Shipbuilding and Repair Co., Limited, Toronto.

These assets, estimated at more than $1,500,000, include a leasehold on the waterfront from the Harbor Commission. The area covers thirteen acres, and has a front of 1,868 feet. The lease, dating from July, 1919, is for 42 years. For the first 21 years the annual rental shall be $22,100.

The buildings and plant, erected three years ago, represent an investment of $1,570,149. There are five permanent shipways, and three electrical gantry cranes.

## WAGE DISPUTES

According to figures just published by the Ministry of Labor, Italy lost 55,000,000 days of work last year because of strikes. This figure includes labor disorders of every kind—wage disputes, loss occasioned by the occupation of the factories by workmen from last July to September and disorders in the farming districts.

Wage disputes caused the major part of the loss, with 16,500,000 days. The Communist agitations of last year when the factories were occupied are calculated to have resulted in 10,000,000 lost days. Political strikes and other suspensions not included in the other classes are said to have lost 15,500,000 days.

The textile workers engaged in 212 strikes, the largest number in any trade, throwing out of work nearly 150,000 workmen. The most costly dispute was that of the transportation workers who had 137 strikes, affecting 241,359 workmen and losing 2,523,057 days of work.

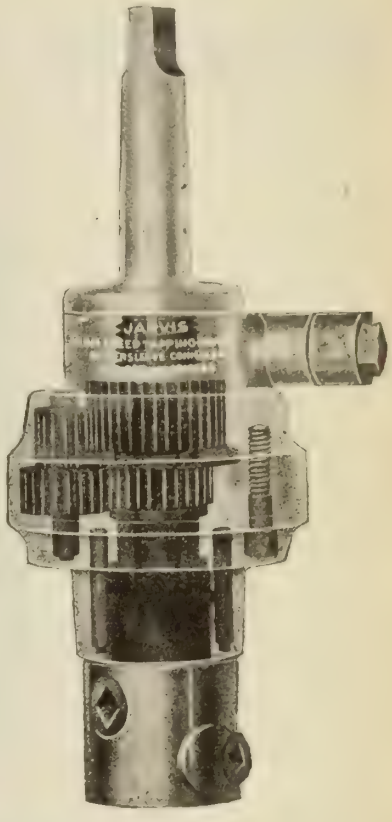
Right on the Lead

# WHY BORROW TROUBLE?

**If you have not reduced your tap breakage to the minimum, you are borrowing trouble.**

Does it mean anything to you that there is a High Speed Tapping Device on the market which is

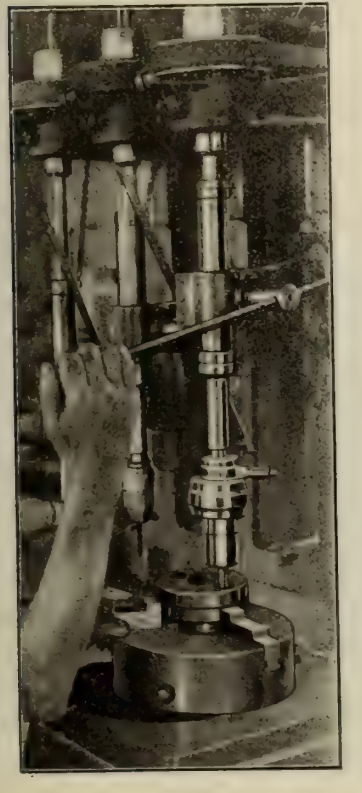
**SUPERIOR**



to any other known method.

Just get these few points now, and then send for the circular which will give you the rest of the story:

There is a Ball Drive and Ball Reverse. You can see how easy this makes the action, with no clinching or binding.



The ball Drive gives direct drive from the spindle to the work. The gears operate only on the reverse.

Reverse motion is much faster than the drive.

Special Taps are not required.

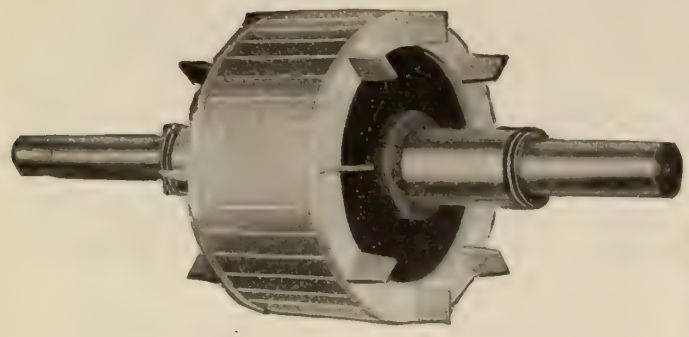
It makes no difference whether the tap is forced against the work in a Drill Press, or the piece is pushed towards the tap in a Speed Lathe.

There are two styles of this Tapping Device. The Positive Style M and the Friction Style N. Where the tapping is in tool steel or any tough metal, or when a blind hole is tapped, the Cone Friction Chuck, Style N, is better.

Seven sizes of this Jarvis High Speed Tapping Device accommodate a range from zero up to 2 in.

And the PRICE—that, too is reduced to the minimum.

---



One more important fact attaches to this Tapping Device. It is recommended and furnished by the Geometric Tool Company as a fitting adjunct to their line of Threading Tools.

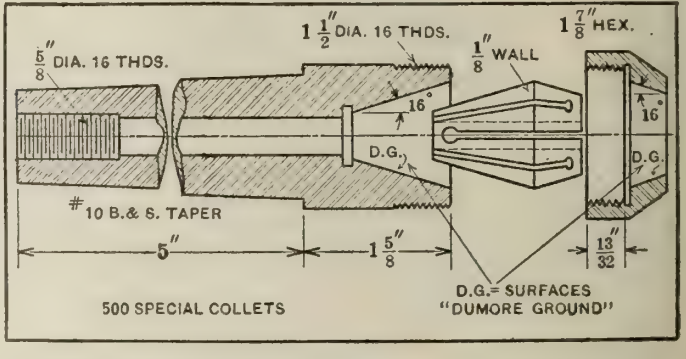
## THE FINEST ON EARTH

# Making Fine Tools

*An Interesting Operation, Economically Performed by Means of a DUMORE Grinder*



This photograph — taken at the City Engineering Company's (Dayton, Ohio) plant shows a Dumore Grinder finishing the main shank and head of a special draw-in collet. There were 500 put through in this special lot and the time for the operation shown averaged 8 minutes per piece.

The second operation; grinding the internal face of the collet nut, was also performed by this convenient precision tool.

Dumore Grinders are popular here as in every plant where fine tools are made. Their accuracy makes them useful for the finest finishing work; their simplicity and convenience make them practical for many difficult, almost inaccessible jobs.

Dumore Grinders transform any lathe into a precision grinder; they make fine finishing possible in every machine shop.

# WASTE IN INDUSTRY EXISTENT FINDINGS AND RECOMMENDATIONS

Speaking on the waste in industrial processes, the recent report of the American Engineering Council's Committee on the elimination of waste in industry, states that this waste is causing enormous annual loss to the United States. What is true there, is equally true here, and following are a few of the points brought out in this report:

The report deals exhaustively with housing and building; ready-made men's clothing; shoes; metal trades, and printing.

**Intermittent Employment.**

The wastes of interrupted production are summarized as follows: "The margin of unemployment amounts to more than a million men; cyclical industrial depressions are causes of waste through idle men, plant, equipment and materials. Intermittent employment is not merely the cause of one of the largest wastes in industry, it is also the one big problem for which labor demands a satisactory solution. Waste results from conflicts between management and labor, but the amount is much less than is popularly supposed. Large inventories of raw materials and finished product and unbalanced production are causes of waste resulting from idle materials. Large sums of money are invested in idle equipment, and over-equipment and factory buildings in many instances are larger than necessary."

In attributing waste to faulty management, the report says: "The average method of management is far behind standards which have demonstrated their practical value; billions of dollars are tied up in idle equipment and there is a large additional waste through maintenance and depreciation charges. Manipulations in raw material result in serious losses and present sales policies are a contributing cause of irregular production." High labor turnover is given as a rough index of one of the commonest wastes in industry.

As to restricted production, the report says: "Both employer and employees restrict output, the former usually by limiting the total output of an industry the latter by limiting the rate of speed of output of individual workmen."

The committee's recommendations for the elimination of waste include the following: "A national industrial information service should be established to furnish more timely, regular and complete information covering current production and consumption and stocks of commodities. A national statistical service should be established covering employment requirements and a national policy regarding public health should be fostered and encouraged. The national program for inustrial rehabilitation should be encouraged and should offer opportunities for education and placement to those having physical defects as well as those handicapped because of industrial accidents. A nation-wide program of industrial standardization should be encouraged in conjunction with industrial interests, and the government should recognize the necessity for a revision of such federal laws as interfere with stabilization of industry." It is also recommended that a body of principals should be accepted which could be developed for the adjustment and settlement of labor disputes.

After outlining the support and help to be contributed by the public and by trade associations, the report takes up the responsibility of plant management. It declares that administrative policies should cover improvement of organization, administrative and management control; the stabilization of production; introduction of effective employment methods; creation of individual or collective research departments; industrial education; curtailment of practice of adjustments, cancellations and returns where customary; development of purchasing schedules; correlation of sales policies with production and accident prevention.

Organized labor was also urged to cooperate to develop a policy for increasing output, and idle material was shown to cause a large loss. The report mentions that the average plant in the metal trades group is from 25 to 30 per cent. behind the best plant in output per employee, while the building industry is given as about 60 per cent. efficient, and the waste in the shoe industry put at about 35 per cent.

A discussion on the report followed. Mr. McClellan a member of the board, representing the American Institute of Electrical Engineers, and F. J. Miller, Bucks County, Pa., representing the American Society of Mechanical Engineers, criticised the report adversely, while L. W. Wallace defended the accuracy of the report. Mr. Miller said that the report gives conclusions without setting out the facts on which the conclusions were based. It charges, he said, inefficiency to large groups of industries in general, whereas it is more than probable that the facts from which the conclusions are drawn apply only to a few individual members of this group. Mr. McClellan said the report did not define the waste alleged nor cite the committee's authority for the charges made.

It was stipulated that the report be sent back to the committee for revision and members of the board are to receive all the information on which the committee based its conclusions and the board members may suggest any changes they may deem desirable to the committee in writing. As soon as completed and approved by the board, the full report will be given out for publication.

# WAGE CUT EFFECTIVE JULY 1st

The employees of the Canadian railway companies have been told that on July 1st they will be advised to accept a twelve per cent. wage reduction. This will affect roughly speaking, about 150,000 men, and the reduction will become effective July 1st.

The reasons given for the decrease are:

1. Inability of the railways to continue present wages, despite short time in shops and elsewhere and the adoption of every economy possible.

2. A deficit of $11,000,000 being earned by the Grand Trunk this year.

3. The action of the United States Railway Labor Board, whose decisions have always been copied in Canada, in declaring a wage reduction of twelve per cent.

The union representatives here state they will report the proposals of the railroads to their respective unions. The men were not told what would happen if they refused the decrease in wages, and when railway officials were asked they replied that they did not anticipate any refusal.

## A. S. M. E. GET A REAL TREAT

The Ontario Section of the American Society of Mechanical Engineers were indeed lucky when the plant of the Steel Co., of Canada was opened up for their inspection on the afternoon of Friday, June 17th.

Over forty members took advantage of the opportunity, and under the guidance of Mr. Givan, the chief chemist, Mr. Hilton, the blast urnace supervisor; Mr. Hilton, the blast furnace supervisor; and Mr. Jeffries, hte chief electrician; the various departments were thorocghly explained.

First of all a furnace being relined was open for inspection, after which the party viewed the ovens used for preheating. The air drying power section was next explained, where considerable time was spent in this most interesting department.

Next came the coke-making section of the plant, and as luck would have it the party were just in time to see an oven of coke being pushed into a waiting car. This company have 80 ovens, these being in two batteries of 40 each, and of course the time of cooking the coke varies upon conditions. However, when the coke is ready here is what happens.

A car is brought up under the oven about to be unloaded, and from the other side of the oven, a large ram or pusher, shoves the complete contents of the oven into the car, which by the way, moves slowly along the track as the coke is being pushed out. Once the coke is all out, off goes the car to the quenching station, where for 50 to 55 seconds a stream of water is played on the burning coke.

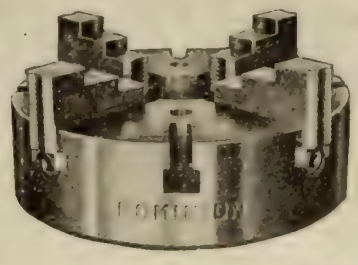
From here the party proceeded to the various by-product sections, where the tar, benzol, amonium, sulphate, etc., etc., are taken out of the gases coming from the furnaces.

The amonium sulphate section was particularly interesting, as in this case the process was easier seen. The material, which is used chiefly as a fertilizer, comes out in the form of a wet pinky white mass. In this condition it is put into centrifugal drying machines where the moisture is taken out, leaving it in a dry powder form.

From this point on, the party went all through the yards, viewing the pig casting machines, the basic open hearth furnaces, the rolling mill dept., and various other sections of the plant.

The rolling mill caught the eye of many. Here was seen huge billets that were handled with perfect ease, and reduced rapidly to any desired size. The wire drawing section was perhaps the most interesting of all. At the finishing point, the wire attained a speed so great that everything is guarded to prevent accident should the wire break or fly out of the guards. The speed at which this wire is drawn is nothing short of marvellous. We would like to deal with each dept. in detail, but space does not permit. Sufficient to say that when the party came to the conclusion of the tour, they all voiced the same opinion, viz., that it had been the most profitable afternoon they had spent in a long time.

### RIVERDALE TECHNICAL SCHOOL.



The tenders for constructional work on the new Riverdale Technical School are now out. Canadian Machinery had the privilege of looking over some of the plans, and the industrial section has been well attended to.

A space of approximately 150 ft. by 172 ft. has been devoted to the various industrial departments; a hallway coming in between the 172 ft. dimension. The rooms used for the different trades are approximately 40 x 32, with the exception of the construction shop, which is still larger. Following are the trades being provided for:

There is a wood turning and carpenter shop; a construction shop with exceptionally high roof, so that even constructional work on houses can be taught successfully, and a brick shop where the art of clay products generally will be taught.

There is also a sheet metal dept., where sheet metal patterns will be made; a machine shop; and a motor mechanics department.

So far no arrangements have been made as to the style of equipment that will be used in the various sections, but we hope to acquaint those interested with full particulars in the near future.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

## FOR SALE

ELECTRIC STORAGE BATTERY LOCOMOtives for sale. Two. 36-inch gauge. Complete and in good condition. R. T. Gilman & Company, Dept. "E," 211 McGill Street, Montreal. (ctfm)

MOTORS FOR SALE — 5 H.P. CAN. GEN. Electric, 2-phase, 60-cycle, 1800 r.p.m., switch starter; 20 h.p., Fairbanks-Morse, 2-phase, 60-cycle, 1200 r.p.m., Auto starter (without low voltage release); 25 h.p., Can. Gen. Electric, 2-phase, 60-cycle, 1000 r.p.m., no starter; 30 h.p., Westinghouse, 2-phase, 60-cycle, 945 r.p.m., Auto starter (without low voltage release); 3 h.p., Westinghouse, 2-phase, 60 cycle, 1700 r.p.m., switch starter; 1 Smart-Turner Triplex Belt-driven Pump, 2 x 3. Box 780J, Canadian Machinery.

## Grey Iron Castings

Light and Medium-Bench and Floor Repetition Castings; Capacity 15 tons per day.
Expert Metal and Wood Pattern Work. Our advice and estimates will save you money.
Semi-finishing operations on Lathe or Grill on Castings supplied if required.
ASK US.

**THE KATIE FOUNDRY, GALT, ONT.**

111 Adelaide St., W. Toronto.
(C 26 M)

PARTIAL LIST

## Machine Shop Equipment

*At Extremely Low Prices*

LATHES—All sizes and lengths of bed. Special price quoted on rebuilt 20 in. x 8 ft. C.M.C.

AIR COMPRESSOR—8 in. x 8in. Chicago Pneumatic.

TANKS—10 Tanks 10 ft. 6 in. diam. x 29 ft. 6 in. long. 19,000 gals.
3 Tanks, 10 ft. 0 in. diam. x 89 ft. 0 in long. ⅜ in. Heads. 22,893 gals.
Full line of other Steel Storage Tanks, open and closed, all sizes.

PUMPS—1 Triplex Power Pump, 1½ in. x 6 in. Hydraulic Machy. Co. Also 1 in. x 5 in. West Tire Setter.
1—Centrifugal Pump, 2½ in. x 1½ in. Gould.
1—Gould Triplex Power Pump, 2 in. x 3 in.

Milling Cutters and Reamers, full assortment, all sizes and shapes, at less than half price. Send us your enquiries.

# Canadian Machinery BUYERS DIRECTORY

If what you want is not here, write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index—last page of book, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

## DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

BURT SLIDING CONE VENTILATOR
WITH FUSIBLE LINK

# SCIENTIFIC VENTILATION

THE need of scientific ventilation in manufacturing plants of all descriptions is being better recognized today than formerly.

Better work, greater production and healthier, happier employees are natural results when factories are equipped with an efficient ventilating system.

"Reed" Engineers and "BURT" Ventilators will satisfactorily solve your ventilation problems.

*May we inspect your plant and submit our recommendations?*

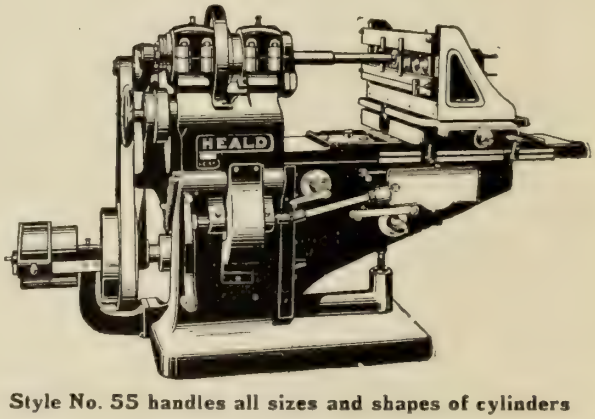
*If what you need is not advertised, consult our Buyers' Directory and write advertisers listed under proper heading.*

# H.W. PETRIE LIMITED

CANADA'S DEPENDABLE MACHINERY AND SUPPLY HOUSE

The "PETRIE" policy represents the standard in high-grade tools and efficiency in service.

# MACHINERY and SUPPLIES



REMEMBER the house of H. W. Petrie, Limited, when in need of anything in the shape of machinery and supplies. A colossal stock of machine tools of every description always on hand from which you are assured of getting the exact tool to suit your requirements. Included in this great array are many used tools. They are in good conditions and warranted to give satisfactory service. If you are seeking an opportunity to buy equipment at rock-bottom price don't fail to see our line of used machines.

**SERVICE.**—A competent staff of engineers is at your service at all times; submit your problems to them; their advice costs you nothing and it is highly authoritative.

Another factor of importance to remember in dealing with the house of H. W. Petrie, Limited, is this: the quickest of service is always rendered on orders large or small.

Get the Cream of a Profitable Business

**Regrinding Cylinders makes used motors better than New**

**Style No. 55 handles all sizes and shapes of cylinders**

There is no business to-day that has the possibilities and which fits as nicely into a small machine shop, automobile repair shop or a concern doing welding, as the regrinding of worn or scored cylinders. Heald style No. 55 is built expressly for regrinding work. It is simple, moderately priced, self-contained, and has a very large capacity and range easily taking care of singles, doubles, four and six en bloc cylinders.

*Over Half a Century of Unequalled Success*

# H. W. PETRIE, LIMITED

You can't help noticing the good qualities of

## Pratt & Whitney Taps

Their free cutting qualities, their extreme accuracy and their extraordinary ability to outlive others distinguish them.

The non-eccentric relief—a distinctive P & W feature—is the secret of their goodness. One-third of the cutting edge is concentric. The remaining two-thirds has eccentric relief. Taps can be sharpened at the only correct point—on the face of the cutting edge. Sharpening in no way effects their size.

Yes, they cost a little more than some others, but they're well worth the difference. Carried in stock as are all other P. & W Small Tools at our sales offices and agencies as listed.

*The Waste You Can See is Least to be Feared*

A HOLE in a dam or a leaky steam pipe is not to be feared; it cries aloud for attention.

It's the hidden leaks—such as excessive weight of pulleys on the bearings—air fanning and belt slippage that steal your power and add to its cost.

How to overcome these losses is explained in our book, "Getting Maximum Pulley Efficiency." Yours for the asking.

**The American Pulley Co.**
**Philadelphia, Pa.**

# AMERICAN STEEL SPLIT PULLEYS

# Have You Any MACHINERY PROBLEMS?

## Our Engineering Staff is at Your Service

OUR Engineering staff understand Canadian Manufacturing conditions thoroughly. Why not put your problems up to them? They are prepared to give you the benefit of their wide and varied experience without obligation. Their advice has been of practical value to others and no doubt they can serve you just as well.

---

When you need anything in Machinery and Supplies remember that we can supply your needs with new or used equipment. There is nothing we cannot furnish in new equipment from our immense stocks—and we also have a lot of good used tools on hand which you should investigate; they are being sold at very attractive prices.

# LA SALLE

## Has an Advantage Over Other Grinders

There is some outstanding feature of all La Salle Grinding Machines that lends it exceptional productive ability.
The American Drill Grinder is especially adaptable for grinding twist, flat and three-lipped drills, because it has automatic lip rest and caliper jaw device, which assures proper clearance on all sizes of drills automatically. Send for descriptive matter covering our entire line of grinding machinery.

Fenwick Freres & Co., Paris, France

# THE JOHNSON FRICTION CLUTCH

## The Case Against the Countershaft

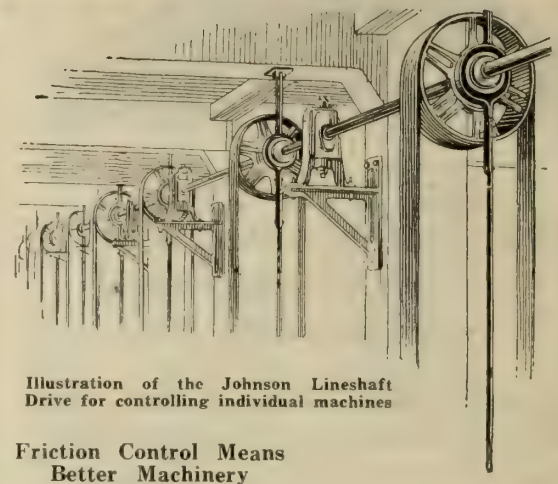
The old familiar countershaft drive, through cross belts and tight and loose pulleys, stands accused of the following offences against efficiency:

1. Involves needless equipment.
2. Costs too much to set up.
3. Prevents economical and systematic use of space.
4. Operates sluggishly.
5. Multiplies belt troubles and the resultant cost of upkeep.

Modern practice has discarded the antiquated countershaft for the simplicity and efficiency of the clutch drive direct from lineshaft.

**Adopt the Johnson Lineshaft Drive**

The economical, efficient and durable method of power transmission through friction control.



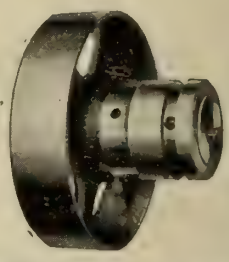


Illustration of the Johnson Lineshaft Drive for controlling individual machines

**Friction Control Means Better Machinery**

Whether it is applied overhead or in the machine itself.

# No Confused Readings

Another advantage in using Starrett Tapes is found in the marked difference in size between the foot and inch figures.

All standard Starrett Steel Tapes have black enameled surfaces with sharply contrasting figures and graduations.

And remember that the markings on Starrett Steel Tapes are *etched into the metal.* Every line and figure is clean cut —permanently easy to read.

Write for the Starrett Catalog No. 22.

Starrett Steel Tapes are furnished in lengths varying from 25 ft. to 100 ft. Graduated in feet and inches on one or both sides; feet and inches on one side, and feet, 10ths and 100ths of a foot on the other; metric measure on one side, or both sides, or metric measure on one side and feet and inches on the other; feet, inches and 16ths of an inch, or other markings, on one side only; and in other combinations of markings. Tapes are supplied with or without cases in various styles.

# KEMPSMITH

## No. 2 UNIVERSAL

Thirty-two years ago the Kempsmith Company began its career in a small one-story frame building. To-day there are four main buildings, aggregating 106,000 square feet of floor area, besides various storage sheds, etc. Every building of the plant is a model of its kind.

It has always been, and will continue to be, the purpose of the Kempsmith Company to produce machines of the highest quality only, suited to the most advanced practice.

Every machine, whatever size or type, is put to test under cuts and conditions purposely more severe than it will encounter in even the most progressive shops and when it leaves our factory it has our positive and definite guarantee back of it.

***Literature will be gladly sent upon request***

# Widen The Scope of Machining Operations

THE Horizontal Boring, Milling and Drilling Machine with its various attachments, is a highly important factor in any plant.

In machining parts requiring a series of boring, milling, reaming and drilling operations, the Landis is noted as a time saver, because these varied machinings can be accomplished with a single set-up of work. With the addition of a universal table, facing heads or other accessories best suited to your work, this boring machine has unlimited possibilities, and at all times can be relied upon to handle the most difficult jobs, accurately and quickly.

*Our catalogue tells more about this powerful tool. Write for it.*

# The Wild Carnival of High Prices is Over

The Printers' Unions of Toronto pay their dues and take their orders from their head office in the United States.

Some time ago they got instructions from their head office in Indianapolis, Ind., to demand shorter hours and more wages, and if these orders were not acceded to, to strike.

The Toronto Publishers and Employing Printers refused to grant these demands. So on June 1st, the Printers struck.

There is no use in the Toronto Printers, or any other body of men, blindly failing to realize that the wild carnival of High Prices is over.

If the members of the Printers' Union go out to buy boots to-day, they do not expect to pay more than they did a year ago.

They demand, and get, cheaper boots.

They are not willing to pay more for clothes, or foodstuffs, or any other commodity.

They expect to pay, and do pay, less.

And the public is not tolerant of any scheme or arrangement which is going to make its printing cost more. It is lower prices they are looking for. Why should printing costs advance, when prices of everything else are going down? That is why the Publishers and Employing Printers are resolutely and unalterably opposed to the granting of shorter hours and more pay, because it, of necessity, means dearer printing, and the public will not buy dearer printing.

That is why we are resisting and refusing to obey the mandate from the United States that the Local Printers demand more wages and shorter hours.

The Purchasing Agents' Association of Toronto at their meeting, held June 8th, 1921, passed the following resolution:

> "We endorse the attitude of the Toronto Typothetae in their efforts to prevent increased cost of printing and deplore the action of some Employing Printers in granting the Unions' demands, which, necessarily will result in an increased cost of production, when at this period economic conditions demand that production costs be lowered rather than increased."

The MacLean Publishing Company are fighting these unreasonable demands not only in the interests of their own business (and this includes the employees who are on strike) but in the interests of business conditions generally.

Good times and healthy business conditions cannot return unless we all do our part to get through the readjustment period in a sane and reasonable way.

# BROWN & SHARPE
# AUTOMATIC GEAR CUTTING MACHINES

## SPEED

Brown & Sharpe Automatic Gear Cutting Machines have demonstrated their ability to meet the most severe and exacting requirements in gear cutting. They are designed to withstand heavy cuts at rapid speeds and coarse feeds.

The illustration shows a typical operation where rigid construction and rapid operation are essential factors. Note the Brown & Sharpe Stocking Cutter in operation, also the use of intermittent indexing, which is advantageous where a more even distribution of heat throughout the blank is desired without sacrificing accuracy or forfeiting cutting speed.

**Roughing out** a 2-pitch gear, 124 teeth, 6 in. face, 5 ft. 3 in. outside diam., on our No. 6 Automatic Gear Cutting Machine.

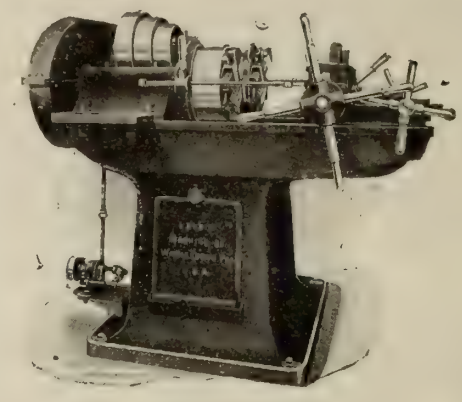
CANADIAN REPRESENTATIVE

**CANADIAN FAIRBANKS-MORSE CO., LTD.**



# Landis Threading Machines

## Standard Labor-Saving Equipment

Landis Bolt and Pipe Threading Machines do better work in less time because of the distinctive design of the Landis Chaser, which operates in the same manner as a lathe tool. Placed at a tangent to the work it allows the machine to operate at a higher speed than is possible when a hobbed type of die if used.

The diagram illustrates the main characteristics of the Landis Chaser as compared with the hobbed type die. It shows the long life of the Landis Chaser, and the fact that both right and left hand threads can be cut with the same set.

These are some of the special features that will help you lower the cost of production. Landis Thread-Cutting Machines are considered standard equipment by leading manufacturers, whose hardest jobs they handle with complete satisfaction.

We are the Canadian Representatives and our nearest Branch will gladly send detailed information.

# Gashing Teeth of a Large Gear on the Slotter

## In Addition to Showing the Gashing of Teeth on a 74 Tooth Gear, the Examples Cover the Cutting of Keyways in Wire Wheel Hubs—Machining a Cross Shaft Bracket—and Slotting Connecting Rod.

DURING the last quarter of a century, unprecedented improvements in machine tool design and manufacturing methods have taken place. High speed steel, and standardization are only two of the important factors that have caused the speeding up of industry generally. The use of high speed steel meant better and more rugged machines to withstand the additional working capabilities of tools made of such metals, and, in many cases special single purpose machines have been brought forward, which are suited for certain classes of work only. We now have the single purpose lathe; the continuous miller of various types, and many other notable special machine tools. These machines have their own particular field, but how about the all-around tool, the one capable of quickly adapting itself to the work in hand. Has such a machine, like the all-around mechanic, disappeared?

Luckily we can answer in the negative, for any mechanic who has watched a modern slotter at work could never grumble as to its versatility. When we say modern slotter we mean modern in the full sense of the word. We do not refer to the antiquated models one sometimes bumps up against in an odd corner of an old-time machine shop, for the slotter of today is just as much a manufacturing tool as any other, with its versatility added.

The design of such machines has been continually improved upon, until they are now able to handle the heaviest or lightest machining operations with equal accuracy. If required for standard work they can be tooled to suit the job, but should the need arise, they are capable of being adjusted quickly to special work of any nature. About as good a method of proving this statement would be to illustrate, and also give word pictures of operations that have been performed on slotters.

Take for example Fig. 1. This shows an operation being performed at the plant of the Standard Roller Bearing Co., who have been using slotters on automobile work for several years. The machine is cutting keyways in Packard wire wheel hubs, and two keyways 5-16 in. wide, and ⅛ in. deep, are cut at right angles to each other in a tapered hole approximately 1¾ in. by 1 5-16 in. The length of the keyway is 5⅛ in., so that the closely confined space in which the keyways have to be cut is readily apparent. Twenty of these hubs are turned out per day, while at a second operation on the same piece, six additional slots are cut, close up to a shoulder.

Fig. 2 shows the gashing of a 74-tooth gear of rather large size. This work is being completed at a gear works plant, and is typical of similar gear work that

*Illustrations through the courtesy of the T. C. Dill Co., Inc., Philadelphia, Pa.

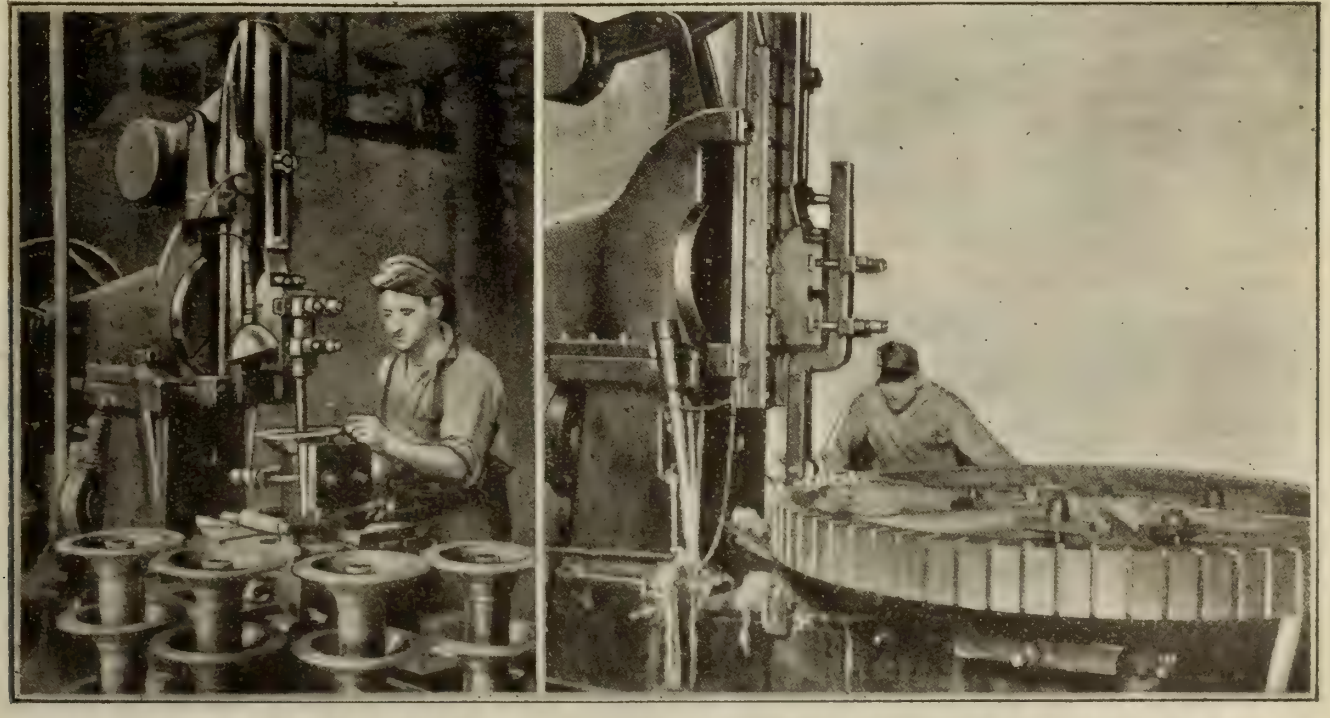

FIG. 1—CUTTING KEYWAYS IN WIRE WHEEL HUBS.

FIG. 2—GASHING THE TEETH OF A 74-TOOTH GEAR.

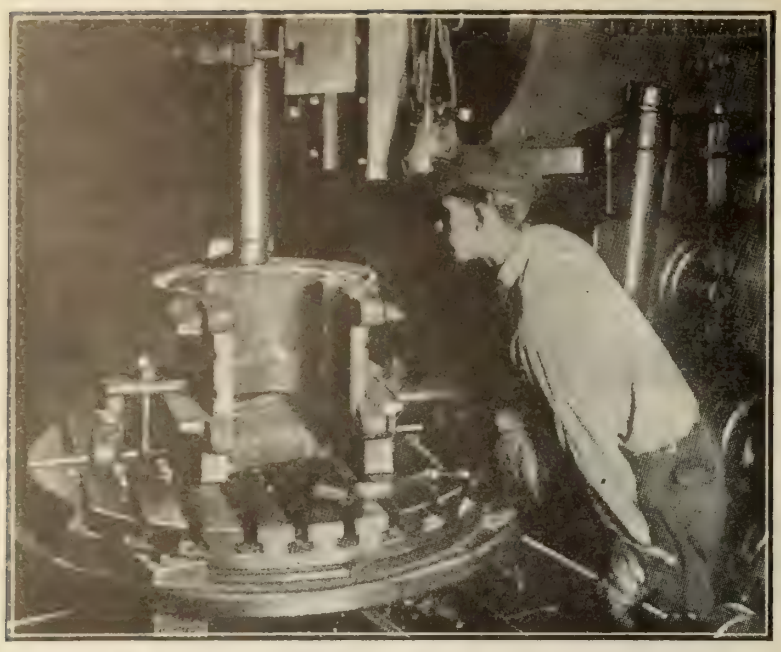

FIG. 5—MACHINING A CAST STEEL DRIVING BOX.

is partially finished on such machines. The particular machine shown had been on this class of work for about a year when photographed.

Fig. 3 illustrates the machining of a big cross shaft bracket, the requirements in this case being to face the base and the two half bearings for the bearing cap location. The series of operations are completed in 55 minutes including time for setting up, so that our former statement about the modern slotter being a manufacturing tool is verified by this production figure.

In a certain structural steel plant they use a slotter for almost a little bit of everything, but here is one job that is rather novel and interesting. They use the machine to put a radius on the end of pieces of angle iron, and a double radius tool takes the cut. The operator sets up two pieces of angle iron at one time, feeds them up to the tool and starts the machine. The time to complete both pieces is two minutes.

In another plant, this time the repair shop of the Wilmington Steel Co., they use a slotter for machining the end of a chain rod for a 25-ton crane. Another job on the same machine that was accomplished just previous to the one we refer to, was the cutting of a 5-foot keyway one inch square, in a blooming mill engine cap that weighed 6,000 pounds. That's why we have termed the slotter a versatile machine.

At another shop the guides in gate valves are machined on the slotter. Running down to the solid bottom of valve, these guides are in a blind cut, thus giving no chance to mill, plane or shape. The slotter in this case met the need nicely.

At the plant of the Shepherd Engineering Co. they used slotters for engine work. On deciding to turn out lathes, they found that the slotters accomplished work on these lathes that even surprised themselves. One of the operations completed was machining the bottom of the lathe tailstocks at the rate of one per hour, floor to floor time. Other operations were completed in like proportionate time.

Railroad shops find slotters very useful. Here are a few of the jobs at present being performed in such shops. In one plant they cut out the slots in heavy forged steel locomotive main drive rods two at a time, while in another shop the side rods of locomotives are machined. One-eighth to one-quarter inch of metal is cut from each side of a ten-inch slot simultaneously, reaching a continuous downward cut of 12½ in. at the deepest point.

Fig. 4 depicts a good example of railroad work. In this case the work is slotting the large hole at the end of the connecting rod shown. In order to facilitate handling, a special supporting truck is used, this being equipped with four caster wheels spread quite a bit apart. Six sides of the holes have to be machined, and when shifting is necessary to bring another section to the slotting tool, all that is required is to roll the truck to a new position.

Another interesting example of railroad work is shown at Fig. 5. The work being machined is a cast steel driving box, and as this box receives the crown brass, or upper portion of a locomotive bearing, it must be accurately machined. As the cutting tool travels up and down, the work is automatically revolved.

In another plant they use a slotter to machine parallel flats on pump plungers. Of course if this operation was to be turned out in quantities, a slotter would not be the best machine to use, but we mention the operation to point out the machine's versatility.

The Philadelphia & Reading Railroad use their slotters for many purposes, but one interesting job is the machining of the crown brasses for a locomotive. The usual method to finish such brasses is to plane the top and bottom, then mount them on an arbor and turn the outside; after which they are again reset and the ends planed to fit the driving box. Here is how they handle it on the slotter.

The top and bottom of the rough brasses are planed as usual, then the radius is marked in the regular manner and lined up in the slotter by means of an indicator fulcrumed on an arbor in center of table. The clamping nut is tightened, and a roughing cut run over the work. A finishing cut follows; then the ends of the brasses are finished, including the off-sets, using the same slotting tool. In other words the work is finished right on the machine. The size of these brasses run from 8 to 13 inches in length, and the slotter time varies from 7 to 22 minutes per piece.

It can be readily understood that the photographs and descriptions given barely scratch the surface of the possibilities of slotter work. One must pass through different types of manufacturing plants, viewing the slotters in actual operations, before they can realize the variety of work that comes to the tables of such machines. This is particularly true of railroad shops, for in one day a slotter often makes the acquaintance of a dozen jobs.

# Some Pioneers of the Machine Tool Industry

## A Short Survey of the Lives and Labors of the Early English Toolmakers. The Method of Making Threads—Punch and Shear Machines—Steam Hammers—Steam Pile Drivers—and Other Machine Tools

By JAMES PEARMAN

THE successful construction of all machinery depends on the perfection of the tools employed, and whoever is a master of the art of toolmaking possesses the key of the construction of machines. The contrivance and construction of tools must therefore ever stand at the head of the industrial world."

As far back as 1851 C. Babbage uttered the above words in a speech at the great exhibition in that year, and the above author uses them very nicely in introducing an article in a recent issue of the "Machine Tool Review," on the subject as above titled. He continues as follows:—

I have long held the opinion that the lives and works—yes, and the triumphs also I may say en passant—of the men who have by their inventions founded our craft as we understand it, have been in the past mainly ignored and their contributions to mechanical science forgotten. In 1851—70 years ago—Mr. Babbage pointed out the importance of our branch of the mechanical art; how much more true it is today the recent war has shown, when statesmen declared that it was "an engineers' war." It is my intention to outline the work of some of the great men who have left their mark on our daily lives.

In the forefront of these I unhesitatingly place Henry Maudslay, who was the inventor of the slide rest and of the screw-cutting and self-acting lathe. Before his inventions, screws of all kinds had to be produced by the most primitive means—in a single word, by hand. The screws, with threads of angular form, were cut with a triangular—or in shop parlance three square—file, and, as may be imagined, had no semblance to form or pitch. In consequence it was necessary to make each nut to suit one particular screw, and it would not mate up with any other except by sheer accident.

### Making Square Threads.

As for square threads, they were made with hammer and chisel and finished by filing. An early authority gives a description of the manner of making the nuts to suit these latter. They were produced, it appears, in the foundry. The screw was first coated with oil and the nut was cast around it, as we do to-day with babbit when we need a quick repair. But with what metal they made their nuts! With lead—and it is easy to imagine the hard and poetical words of the early mechanic when he had to separate the two.

Think of the work in "chipping" with a cross cut around a round bar. It is enough to make a present-day mechanic tremble. Happily it is not necessary, thanks to the labors of Henry Maudslay, who solved the problem for us.

Henry Maudslay was born in the seventeen seventies at Woolwich in a house in an alley at the rear of the Salutation Inn, which was nearly opposite the Arsenal gates. He commenced work in the Arsenal as a powder monkey, filling cartridges at the early age of twelve years, as it was then the custom to begin young so as to contribute something to the family coffers. Two years later he was transferred to the carpenter's shop, where he first became acquainted with tools and the art of working in wood and iron.

The blacksmith's shop was close to the carpenter's, and young Maudslay would often stray away from his job to watch the smiths, for, as he remarked in after years, his heart was always in metal working instead of wood. So strong was his leaning towards smith's work that his foreman eventually got him moved to the smithy at his own request. Here he was in his element, and his heart being in his work, he soon made rapid progress, becoming at 18 years of age one of the best smiths in the shop. So skilled was he that he soon became to be spoken of in the London shops as one of the most dexterous hands in the trade.

**IS THERE ANYTHING NEW?**

Joseph Clement, who was born in 1779 was really the founder of processes and of systems of standardization, which others following him have claimed as their own.

In 1828 he began the making of fluted taps, and he performed the fluting operation by means of a revolving cutter running on an arbor between the lathe centers.

Joseph Bramah, who had invented a series of locks, was about this time in search of someone to help him out in the manufacture of them, as he found great difficulty in getting them made in sufficient quantities. In his dilemma he consulted an ingenious old German, who was working in Whitechapel, but they could not solve the problem, so someone in the shop suggested putting it up to Maudslay. Maudslay was called in, and although a very young man, successfully solved the problem, and became foreman and afterwards general manager. He was soon looked upon by all who did business with him as "Bramah's right-hand man."

I may say in passing that at no time during his stay at this place did he receive more than $7.00 per week. It was while Maudslay was with the Bramah concern that he invented the cup leather that is used to this day in hydraulic and pneumatic cylinders without any alteration or improvement although a century has elapsed. Bramah was the father of the hydraulic idea, but he could find no means of preventing water from passing the piston. Maudslay suggested that a bit of leather squeezed up like a cup would hold all right. This was done, and has never been improved upon.

Whilst he was there he married his employer's servant—Sarah Tindal—and, as he afterwards said, he found in her an ideal helpmate. Some time afterwards he decided to start on his own account, which he did in 1797, in a small shop and smithy in Wells Street, Oxford Street. He found the place in an awful state, but he and his wife cleaned it up, and in two days he was ready to start. His first customer was an artist, who required some art metal work done, which he executed to his patron's complete satisfaction.

At this time he was devoting his time to improving the primitive machine tools which then existed. It was whilst he was following along this line that he made his first important discovery—namely, the slide rest. It was in the Bramah shop that he first made this epoch-marking tool, where it continued to be used long after he had left the works. "I have seen the slide rest," says Mr. James Nasmyth, the inventor of the steam hammer, "the first that Henry Maudslay made, and in it were all those arrangements which are found in the most modern rest of our own day, all of which are the offspring of that of Maudslay's original. If this tool be still extant it ought to be preserved with great care, for it was the beginning of those mechanical triumphs which give to the days in which we live so much of their distinguishing character." (1853).

We find that the French as a nation were very skillful in turning, and an elaborate treatise was published in Paris in 1754 by one Jean Plumier called "L'Art de Tourner" (The Art of Turning). It was after Maudslay had developed his idea and produced his screw-cutting and self-acting lathe that one of the French refugees from the revolution of '93, named M. de Bacquancourt, was passing the little shop in Wells Street and was attracted by a fine specimen of screw-cutting exhibited in the window of the shop. Being himself an amateur turner, he stepped into the shop to inquire as to the method of its production, and was so struck with the personality of the young craftsman that he introduced him to one of his countrymen—M. Brunel—who had important work on hand for the British Admiralty. Of this man more anon.

Orders followed quickly after this, and Maudslay had to remove to larger premises in Cavendish Square. This again became too small, so he took a building which had been a riding school in Westminster Road, Lambeth, and founded the celebrated firm of Maudslay Field & Co. Here he took in hand the improvement of the steam engine, especially that of the marine engine, the type in use until the steam turbines came along. The engines for the "Regent," the first boat which plied between London and Margate in 1816, established his reputation as an engine builder.

### Punch and Shear.

Another of his inventions was the punching and shearing machine, exactly as used to-day in all shipyards of the world, by means of which he reduced the piercing of plates for cooling tanks from about $2.00 per tank to 18c. He continued to devote himself also to the development of the lathe, which he regarded as the master machine, which indeed it is; the other machine tools are but modifications of it.

In his system of screw-cutting with taps, dies etc., he laid the foundations of all that has been done in this essential branch of machine construction. Many men who have since made their mark, such as J. Whitworth, J. Clement, J. Nasmyth, were trained in his shop. Mr. Nasmyth says of him "that you could see the man's character reflected in whatever work he turned out, and as a connoisseur in art will exclaim 'This is Turner' or 'This is Reubens' at the sight of a picture, so would a mechanic of that day say of a piece of work, 'This is Maudslay'."

Every mechanical idea that he studied was brought forth from his hand re-arranged, simplified, and made new. He at once stripped the subject of all unnecessary complications, for he had a wonderful faculty of knowing what to do without, which is as necessary sometimes as knowing what to do with.

Mr. Nasmyth goes on to say that "It was a special and constant practice with him on a workman's holiday or on a Sunday morning to take a walk through his workshops when all was quiet, and then and there examine the various jobs in hand. On such occasions he carried with him a piece of chalk with which he would record his remarks in the most pithy terms. Any want of setting things square or in "flat filing," which he held in high esteem, or in not sweeping down the bench and putting the tools in order, was sure to have a record in chalk made on the spot. These chalk jottings were held in the highest respect by the men, whether in praise or blame, as they were sure they were deserved, and when the men next assembled it soon became known who had received the honor or otherwise from the master.

He died on February 14th, 1831, and was buried in Woolwich Churchyard in a cast iron tomb made to his own design. He was always proud of his connection with Woolwich, and Woolwich had good reason to be proud of him.

### Founder of Standardization.

Another man who followed close upon the heels of Henry Maudslay in invention was Joseph Clement, the founder of processes and of systems of standardization which other men following him have claimed as their own. Joseph Clement was born at Great Ashby, in Westmorelandshire, in the year 1779. His father, though only a weaver, was a man of culture and education, being, however, entirely self-taught. He was an ardent student of natural history; his great speciality was entomology, to which he gave most of his spare time.

Old Clement was also an amateur mechanic, and such leisure time as he did not devote to his nature study was employed in working at a lathe of his own crude construction on which he used to turn his bobbins. His son Joseph was set to work at a very early age, and received little education. He was, however, a lad of character and determination, and saw the necessity of education. He made up his mind to educate himself, as far as he was able, during his leisure hours.

His father needed his help at the loom, where he worked for some years. As trade became bad in that line of business, at the age of 18 he became a thatcher, and followed that calling until he was 23. He made a friend of the village blacksmith about this time, whose smithy he used to frequent, and there learned to handle the hammer and file. A cousin of his named Farer, a clockmaker by trade, having returned to the village from London, brought with him some books on applied mechanics, which he lent to Joseph, and this decided his future career.

He found employment in a small factory at Kirby Stephen, some thirteen miles from Great Ashby, where he worked at building power looms. His next move was to Carlisle, where he worked on the same class of machine, afterwards going to Glasgow, where he made the acquaintance of Peter Nicholson, an architectural draughtsman and a noted writer on these topics. He took lessons in drawing from this man, and soon became proficient. He was one of the pioneers in mechanical drawing, and for some years stood out alone, as mechanical drawing was an entirely new branch of study.

**LOCOMOTIVES IN 1836.**

Nasmyth was born in 1808, and in 1836 built twenty large express engines in record time, earning an additional bonus for his firm. This attainment later led to the invention of the steam hammer and the story of its development is worth reading. The steam pile-driver was another of Nasmyth's inventions.

Towards the end of 1813, having saved roughly $500.00 out of his wages, Clement resolved to go to London to improve himself in his trade. He obtained employment at Mr. Alexander Galloway's, in Snow Hill, Holborn, where he worked at the lathe. He found that the tools used in the shop were so bad that it was impossible to execute satisfactory work with them. He at once went to the forge and began making a new set for himself. The other men in the shop, to whom such a proceeding was entirely new, came round to observe his operations, and were much struck by his manual dexterity.

He created such an impression, and the work he performed with his own tools was such a revelation that he was soon recognized as the best mechanic in the shop. He did not stay long, however, at this shop.

He called on Mr. Bramah at Pimlico (where he had been preceded by Maudslay). He took some of his drawings with him, and after examination of these, Bramah engaged him for a month, after which he became his chief draughtsman. Whilst here Clement displayed much ingenuity, taking great pride in upholding the standard of excellence for which Bramah's was then noted. At the death of Mr. Bramah, Clement transferred his activities to Maudslay and Field's, where he held the position of chief draughtsman. He did a great deal in the design of the marine engines for which they were becoming famous.

### He Could Save.

As he always had a desire to commence business on his own account, and being a man of very frugal habits, by 1817 he had saved roughly $2,500. Encouraged by the Duke of Northumberland, who was an excellent amateur turner and a frequent visitor to Maudslay's, he decided to launch out on his own, and took a small workshop in Prospect Place, Newington Butts, London, where he began business as a consulting engineer, maker of instruments and small precision machinery. From the time when he took lessons in drawing from Nicholson at Glasgow in 1807, he had been steadily improving in his technique, and he was regarded by general consent to be the finest exponent of this art, which he regarded as being the A.B.C. of engineering. So skillful was he that when the Royal Society required any drawings made of any intricate device, which was to be discussed at any of their sittings, Clement was always the man selected to put their ideas on paper. In 1818 the Society of Arts awarded him their gold medal for his instrument which he had invented for drawing ellipses.

Nothing pleased him better than to have a tough job to tackle, as it stimulated his inventive faculty. In 1820 he was working upon a device for regulating the speed of the lathe when taking facing cuts on work of large diameter. As is known to everyone who has worked on the lathe, as the diameter of the work decreases, owing to the tool getting nearer the centre, so the surface speed decreases also. Clement saw this, and his improved lathe had a device for accelerating the number of revolutions per minute in accordance with the diameter of the work being performed. He was awarded the Society of Arts Isis medal for this achievement in 1827.

Next year he gained their Silver medal for yet another improvement to the lathe which was known as the "Clement's Driver." This was a balancing device which drove on both sides of the centre at once and with equal pressure on any piece of work done between centres.

The writer worked on a lathe with such a driver when a lad, and although the device had much to recommend it, it has apparently dropped out of use. To use the "Clement Driver" the turner had to use a special double-tailed carrier, and this manner of transmitting motion was particularly useful where long and slender pieces had to be machined.

### The Making of Fluted Taps.

In the year 1828 Clement began the making of fluted taps, and he performed the fluting operation by means of a revolving cutter running on an arbor between the lathe centres. This cutter he called a mill-wheel, because of its resemblance to the wheel of a water mill, which was in general use at this time as a means of generating or transmitting power. The development of this mill-wheel is our own familiar milling cutter, which takes such a large part in all kinds of manufacturing and tool-making processes to-day. This, I think is the first time this type of tool is mentioned in Mechanical History, and the results arising from it have surpassed the wildest dreams of its inventor.

His next invention was the headless tap, which makes it possible to pass a tap right through a piece of work without backing out, and which Mr. Nasmyth says is so valuable an invention that "if he had done nothing else, it ought to immortalize him among mechanics." This is in use every day in every engineering shop in the world.

Another of Clement's inventions was the planing machine. Up to this time the method of producing a flat surface in metal which was too large to swing in the lathe was to chip it all over by means of hammer and chisel, and finish the surface by filing. This, as may be imagined, was a very cumbrous and lengthy operation, involving quite a lot of muscular energy and manual skill. He prepared no models of his machine, but made it direct from his

own working drawings, and it was so well constructed that it went together without a hitch, and continued to work until forty years afterwards, which is pretty good proof of the soundness of its construction. Mr. Clement took out no patent for his invention, so that we find no record of it at the Patents Office, as in the case of most other inventions which have revolutionized our craft, but a very complete account of it is to be found in the Transactions of the Society of Arts for the year 1832. (Transactions of the Society for the Encouragement of Arts, Vol. XLIX, Page 157.)

The great value of the planing machine induced the Society to apply to Mr. Clement for permission to publish it, and Mr. Varley, a noted writer on mechanical matters, prepared it. The machine, it appears, was constructed on somewhat different lines from those in use to-day. The table ran on roller bearings, naturally of a very primitive kind. The writer in the "Transactions" says that "the rollers on which the planing machine travelled were so true that if you put a paper shaving under one of them it would stop at once all the rest."

As it was the only machine of its kind it was very much in request, and was kept running day and night. It may be imagined that it brought in a very good income for its owner, as it took work up to six feet square and the charge for planing was roughly $90 per square foot.

Another important departure which he made was in the standardization of screw threads. Until this time, each manufacturer would have his own fancy pitch and form (such as it was), and indeed it was common to find (so the writers of the period tell us) that on an engine bolts of the same diameter would often have various pitches. Clement's orderly mind soon saw the drawback of this, and he therefore laid down standards, which Mr. Whitworth, who was a journeyman in his shop, copied, elaborated and developed, and in after years claimed as his own. Clement was ahead of all the men in his line of business in his own time, and although he was a super-mechanic he had very little business or commercial acumen. He was a heavy-browed man without any polish of manner or speech, for to the last he continued to use his strong Westmoreland patois or dialect. He was not educated in the literary sense, for he read but little and could write only with difficulty. He was eminently a mechanic, and had achieved his exquisite skill by observation, experience and reflection. His head was a complete repertory of inventions on which he was constantly drawing for the improvement of mechanical practice. Though he never had more than 30 workmen in his shops, they were all highly skilled, and the example which Clement set before them of extreme carefulness and accuracy in execution made his shop one of the best schools of its time for the training of thoroughly accomplished mechanics. Mr. Clement died in 1844, in his sixty-fifth year, but his works live on, and have helped along what we call civilization.

The following notes deal with the lives of two men—James Nasmyth and Joseph Whitworth—both of whom were associated with Maudslay and Clement. They both contributed their quota to the advancement of mechanical arts, each in his own particular manner, and both gave great impetus to the engineering trade by the invention of labor-saving tools and processes.

James Nasmyth was born in 1808 at York Place, Edinburgh. From boyhood he had a great desire to become an engineer. During a visit to Edinburgh in 1817 James Watt called on Nasmyth Senr., who was an artist. He had such a story to tell of the success of his steam engine that filled James with enthusiasm and decided his career. His father fitted up a little workshop for him, and as he had a natural gift of mechanical ability, he spent most of his time in constructing models.

He went for a time to Messrs. Carmichael's at Dundee, and whilst there he heard from several of the leading men of Maudslay's in London, of the wonderul work which was being carried out in the workshops of that firm. His father had been introduced to Mr. Maudslay some years before, so he brought his son to London, by boat (there being no railways available between the two cities at this period), and called at the works at Lambeth. The result was that Mr. Maudslay engaged him as his own personal assistant, after inspecting some of the models and drawings that he had brought with him. He felt that in the position which he now held all external obstacles to his progress were removed and that his success in life depended solely on his own exertions. He determined that efforts on his part should not be wanting to make the most of the golden opportunities which he enjoyed.

Nasmyth's workshop life brought him other advantages than practice and technical knowledge. He enjoyed an occasional conversation with not a few distinguished men whose business or tastes had made them acquainted with Maudslay and who came from time to time to consult with him or to talk over matters of common interest. Amongst these were Sir Samuel Bentham, Mr. Barton (Superintendent of the Royal Mint), Bryan Donkin (who was associated with Barton and Maudslay in fixing the standard yard, and who was also the leading authority on the properties of steam), and Sir Marc Isambard Brunel, the celebrated Frenchman mentioned earlier in the article, who was the constructor of the Thames tunnel from Wapping to Rotherhithe.

Nasmyth stayed with Maudslay, Field and Co., until after the death of Mr. Maudslay in 1831. He then commenced on his own account in Manchester. He rented a large flat in a factory building, and started making and repairing all kinds of engines and machinery, but his chief business was in designing and building machine tools. These latter were so well designed and made, that their fame spread far and wide, and orders flowed in very quickly. Soon the premises became too small to accommodate the increasing trade.

He therefore built a factory at Patricroft, on the Bridgwater Canal, in 1836. This he called the Bridgwater Foundry. As the business still continued to grow very rapidly, he took into partnership a gentleman named Mr. Holbrook Gaskell, whose business it was to look after the commercial side of the concern, and the firm became Nasmyth and Gaskell. As the railway boom was at its height at this time, Nasmyth and Gaskell turned their attention to the construction of locomotives with great success.

The Great Western Railway Company invited the firm to tender for twenty of their large express engines, and offered a bonus of $500 per engine beyond the contract price if at the end of a month they proved entirely satisfactory. The firm supplied the engines and won the promised reward.

### The Steam Hammer.

This connection with the Great Western Railway Company is very important, because it led to Nasmyth's greatest invention, the celebratd steam hammer, with which his name is everywhere associated. This is the story of its invention.

The large paddle steamship "Great Western" had proved so great a success that the Great Western Company decided to build another of even larger dimensions, and the machinery for it was partly constructed when a difficulty arose in forging the crankshaft on which the paddle-wheels were to be fixed. With the hammers in use at the time it was impossible to forge so large a mass of iron. The matter was referred to Nasmyth by the chief engineer of the Company, with the result that after careful thought he sketched out in a book which was kept by him, and which he called his "scheme book," the first plan of his steam hammer. This was on 24th November, 1839. He communicated the particulars of his idea to the engineer of the company who was delighted with it, as were also the directors of the company. It would certainly have been made and used, but just at this juncture the Company decided, on the advice of M. Brunel, to adopt the screw propeller, which had just been invented, and the large shaft was not required to be forged. Mr. Nasmyth sent drawings of his labor-saving tool with descriptions of its use to the leading ironworks in the kingdom, but whilst he received many congratulations he got no orders, so the steam hammer stood in abeyance for a time.

There were many visitors, both English and foreign, to the Bridgwater Foundry who came to inspect and buy machine tools. Amongst others there had called one day, when Nasmyth was absent on business, M. Schneider, proprietor of the great ironworks at Creuzot, in France. (The elder of my readers will remember that the guns used by the Boers in the siege of Ladysmith, called at the time "Long Toms," were made at these works.) He was accompanied by his manager, M. Bourdon. After they had visited the works, the "scheme book" was shown them in the office, with the design of the steam hammer in it. Of course Nasmyth was informed of their visit, but the inspection of the "scheme book" was not mentioned, being a matter of every-day occurrence.

In 1842 Mr. Nasmyth was requested to inspect the French arsenals and dockyards and to suggest improvements in the methods of manufacture. Happening to pass near the Creuzot Ironworks, he took the opportunity of paying them a visit. M. Bourdon showed him over the works. Amongst other things he noted was an enormous crank for a marine engine, and, being struck by its size, he asked how "they managed to forge it." Great was his astonishment when he was told that it was forged by his own steam hammer! M. Bourdon explained that he was much struck by the design in the "scheme book," and when he returned to France he had tried it out with great success.

This lent an unexpected interest to Nasmyth's visit, and he was at once taken to see the steam hammer at work, the offspring of his own brain. The success which he had predicted in the working of the machne was fully realized in practice, and he took out a patent for it in June, 1842. Hundreds of these were afterwards constructed at

the Bramah Foundry and sent to every part of the civilized world.

Another of his many inventions was that of the steam pile-driver. This was tried out at Devonport Dockyard, with the result that a pile which took twelve hours to drive by the old methods was driven home in four and a half minutes, effecting a saving of 11 hours 55½ minutes per pile.

He retired from business in 1859 and lived to a ripe old age. He was (in common with other men that have made their mark in industry) never without a hobby, his chief pastime during his retirement being the study of astronomy upon which he obtained recognition as an authority.

Joseph Whitworth was born at Stockport, in Cheshire, on December 21st, 1803. He commenced work at the age of 14 in a cotton mill in Derbyshire, belonging to his uncle, and there he made his first acquaintance with machinery. After four years of this he was transferred to a Manchester workshop. Here he worked to such good purpose that when in three years' time he removed to London he was able to hold his own in the famous workshops of Maudslay and Clement, where he was esteemed as a very clever workman. It was in these shops that machine tools, and the methods of their manufacture, could best be studied, and Joseph Whitworth soon showed that he appreciated the importance of perfect tools as the fundamental condition in the production of perfect work. He readily grasped the fact that all machine tools for the production of plane surfaces were merely copying machines—that is to say, that the surfaces produced were but copies of the truth or otherwise of the slides that the work or tool, as the case may be, moved upon.

### Machine Tools.

He set up in business on his own account in Manchester in 1833, and he advertised himself with no more pretentious title than "Joseph Whitworth, Toolmaker, from London." He commenced building a complete line of improved machine tools, and he found that the production of truly plane surfaces up till that time was an impossibility. The method then in vogue was to plane the pieces and then correct the surface by filing and finally by rubbing two surfaces together with emery and oil between them—in other words, lapping them. This method he found to be very slow and produced poor results. The idea of scraping occurred to him, and he tried it out himself with three plates in the now well known way and produced three practically perfect plane surfaces.

Since then (1840) this method has been adopted in every engineering and toolmaking shop in the world. When he first introduced scraping into his workshops his workmen were very hostile towards what they called a new-fangled scheme. However, he soon won them over, and afterwards they were loudest in their praise of it.

As mentioned previously, Clement had standardized a system of screw threads, but he never published the results. Whitworth elaborated the idea, and laid down the formula for the thread system which bears his name. He was the first man to realize that to produce first-class work it is necessary to work to "fine limits," as we call it to-day. He set about producing a perfect screw, and as it is an impossibility to produce a mathematically perfect one, he worked until he had produced one of sufficient accuracy for his purpose. He made the first measuring machine that embodies the idea of measuring by means of a screw. It will be seen from this that he was the father of the micrometer caliper.

He made a machine to measure one-millionth of an inch, and he exhibited this at the Great Exhibition of 1851. For further particulars of this machine I would refer my readers to Prof. Shelley's "Workshop Appliances," pages 8 to 13. Though this work is somewhat out of date, still there is much in it that has now become mechanical history.

In the year 1868 he offered $500,000 for the advancement of technical education, and he endowed the famous scholarships which bear his name. For this he was created a baronet. His achievement may be summed up in the words of a writer of the period (W. T. Jeans in "Creators of the Age of Steel"): "This celebrated mechanician has invented a whole set of machine tools that have revolutionized the labors of our workshops. He has also invented means for improving the metal from which the tools are made, and has provided for the improvement of that technical education upon which depends the success of future generations in the skilful use of tools."

## VALUE OF EXPERIMENTAL WORK.

SPEAKING of their experimental work, and the value of this department to them, the Alfred Herbert Co. make some interesting comments. They claim that the experimental department has been of the greatest value in determining the best materials to use on machines, also the best allowances for the various fits. They continue as follows:

By the use of suitable experimental apparatus we have been able in many cases to give a machine, in a few hours, a test which would be equivalent to many years' working under ordinary conditions, and have thus been able to arrive at conclusions very much more quickly than by the ordinary method of trying machines out in the customers' works. The result is that in some cases constructions which might be criticized by casual observers are retained in use because exhaustive experimental tests have definitely proved them to be satisfactory.

Here is an example of a test of this kind which was made on the forward and reversing clutches of a 6½-in. single pulley head as fitted to two of our machines.

In the early days of single pulley heads trouble was experienced with friction clutches, partly owing to the material from which they were made, partly owing to the methods of machining and the allowances for fit and wear. The tests in question were made with clutches of various materials, and the particulars given refer to one series of tests.

A special reversing lever was fitted to the headstock and was connected to a simple worm driven crank motion rigged up for the purpose and driven by a pulley from overhead so as to reverse the spindle 18 times per minute. In order to thoroughly test the reverse a very heavy pattern chuck was fitted to the spindle, the weight of the chuck being 105-lbs. and the momentum such as to severely stress the friction clutch at the moment of reversal.

At the beginning of the tests the chuck speed was 224 r.p.m., and it was noted that after 1,620 reversals the clutches became very hot but caused no trouble. After 3,783 reversals the reverse clutch was adjusted and the head restarted, the chuck speed being raised to 334 r.p.m., which was continued throughout the entire tests. At 6,923 reversals the forward clutch was adjusted. At 10,163 reversals the reverse clutch was again adjusted.

At 12,323 reversals the clutches were taken apart and examined; it was found that the friction rings and shells showed no appreciable signs of wear except at the corners of the rings, where slight wear was evident due to lack of roundness when sprung open. The clutch parts showed some signs of over- heating, so the speed of reversal was reduced to 8 reversals per minute, the chuck speed being as before, 334 r.p.m.

At 47,483 reversals the forward and reverse clutches were adjusted and the head taken to pieces for examination and cleaned out. The clutches were in good condition, and the grinding marks in both rings and shells were still visible. At 57,923 reversals the forward and reverse clutches were adjusted.

The machine was then run until the number of reversals reached 101,603, which was considered sufficient, and the test was terminated.

On inspection of the clutches they were still found to be in excellent condition, the only wear in the rings being near the corners, where expansion is at a maximum, and grinding marks were still visible in both friction rings and shells. During the whole of the tests the forward clutch was adjusted five times and the reverse clutch six times.

The head was reversed 43,680 times after the last adjustment of the clutches, there being no further need for adjustment, and the clutches were in good condition at the end of the tests.

The above tests represented one stage in the progress of the friction clutches in question, further improvements having been made later on and further tests of a similar character carried out.

The conditions under which these experiments were made were very much more severe than anything which could take place in practice, as reversal of these heads in practice is only an occasional operation, and the heating effect caused by the constant reversal at high speed with a heavy chuck on the spindle would never take place in ordinary practice.

The knowledge that experiments of this kind gives us is of the greatest value in ensuring that our machines shall work in a satisfactory manner after leaving our works, and results in something of value in the machine which cannot be represented by catalogue particulars but only by the reputation of the maker founded upon the performance of the machines in the works of the user.

---

## GOOD WELDING JOB

The joints in a long gas main of 12 in. and 16 in. steel pipe, laid near Philadelphia, U. S. A., were made with the acetylene blow pipe before the pipe was lowered into the trench. Sections about 300 ft. long were thus joined up, and the pipe was rolled over as the welder worked, to bring it into a convenient position for him. The sections were tested and subsequently welded together in the trench. It is said that rolling over the pipe effected a considerable saving, as compared with welding without turning, and that the joints cost only about 50 per cent. as much as screwed joints.

# WHAT OUR READERS THINK AND DO

## GRINDING THE PROFILE OF DISC CAMS.

By G. LAIDLER

In making tapered poles for wagons or agricultural implements it is necessary to have several sets of cams on the machine for feeding the cutters. A typical pole is shown at the lower left of Fig. 1 and the cam arrangement is seen in Fig. 2, with the details shown in Fig. 3. Each set consists of two planing and two chamfering cams, operating cutters on either side of the pole while it is passing through the machine. The planing cutters operate in advance of the chamfering cutters, the cams for the latter having a relieved portion A B C which keeps the cutter clear of the work until the point of entry C is reached. As the poles are uniformly tapered, the working portion of the cams is made with a contour of a volute, or curve of uniformly increasing radius, and it is essential that all cams of a set be smoothly finished and with the same rise per degree. The cams are made of cast iron and designed with two cored slots D D, diametrically opposite. After being machined the cams are cut in halves through the cored slots, so that they may be easily mounted on the cam shaft, set for timing, or exchanged for other sets, the sections being securely locked by means of retaining nuts and collars.

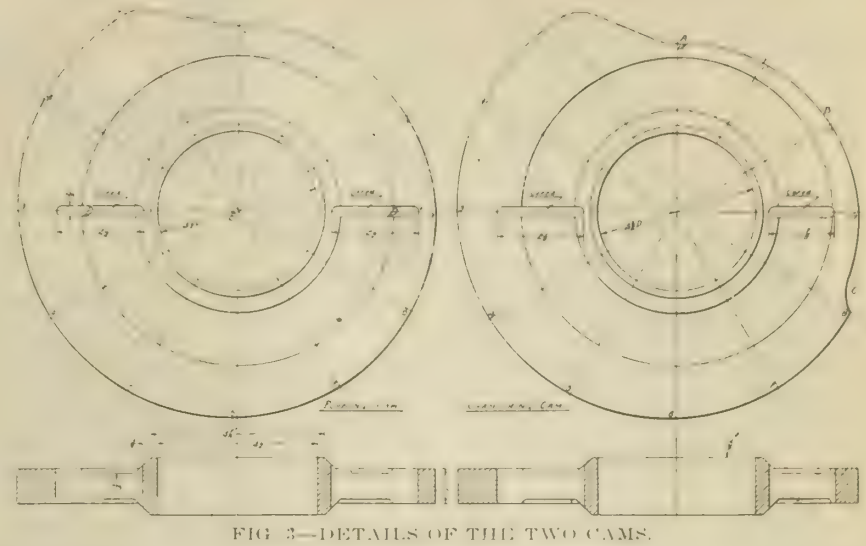

FIG. 3—DETAILS OF THE TWO CAMS.

Although "third place" accuracy of profile could be obtained by milling the working portion of the curves in a universal milling machine with spiral head attachment, it was found better to make an accurate pattern and to finish the profile by careful grinding on a hand operated fixture. A sheet steel template, shown to the right of Fig. 1, was laid off in 15 degree sections with the proper rise per degree. Each pair of points was connected by a curve of single radius. On filing to the line thus drawn a tolerably accurate volute was obtained. This curve was made to overlap the complete circle by 30 degrees, as shown, and a large central hole cut out in the sheet metal pattern. The patternmaker then builds up his pattern blank leaving a turned portion in the centre to fit the hole in the template. After marking off the maximum radius E F in Fig. 3, to his contraction rule, he placed the template over the pattern and turns the template counter clockwise until the larger part of the curve and the point in question coincide. He then scribes off the curve as far as the cam requires it, and finishes the pattern to this line, allowing no draft.

Due to imperfections in moulding the periphery of the cast cam may be lumpy or otherwise untrue. After machining the faces and the bore the cam is

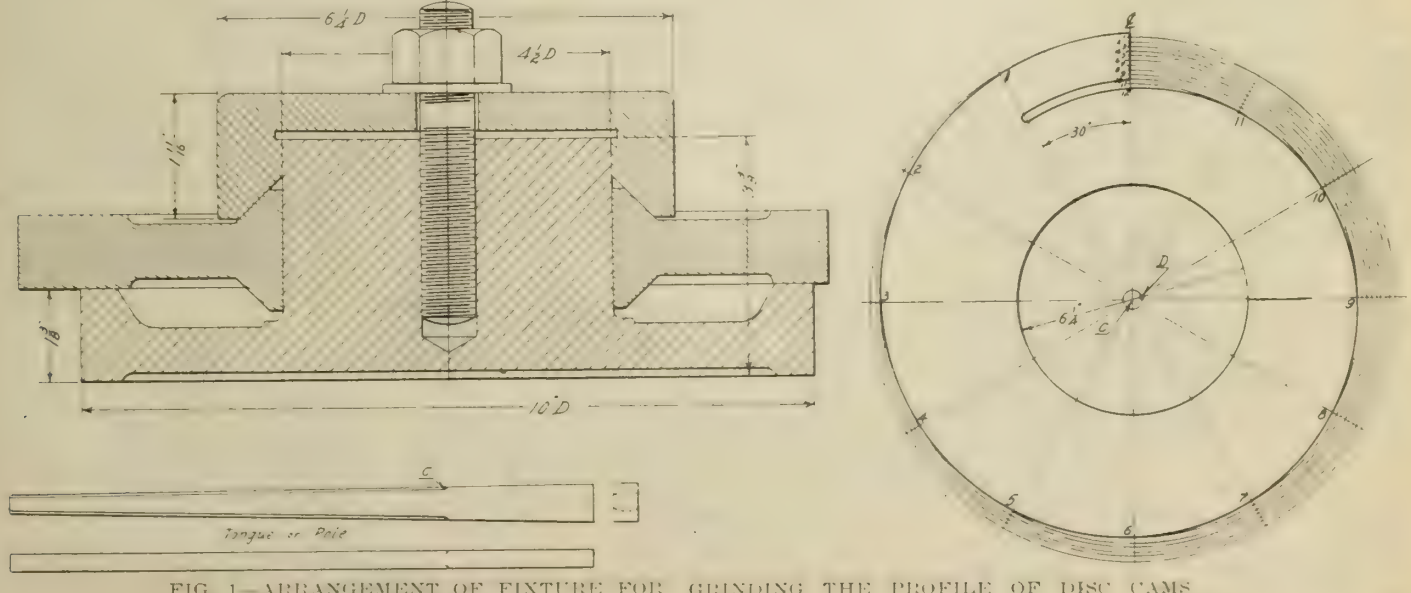

FIG. 1—ARRANGEMENT OF FIXTURE FOR GRINDING THE PROFILE OF DISC CAMS

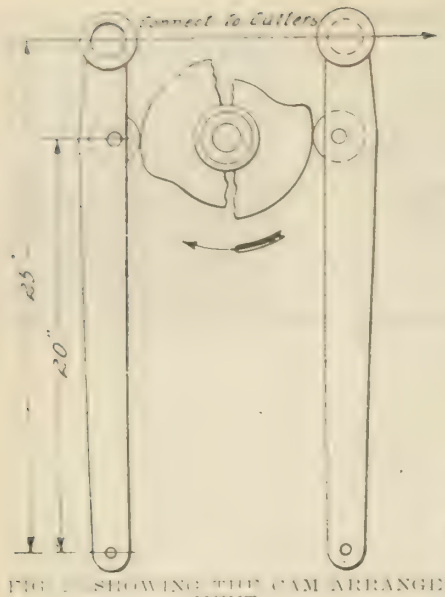

FIG. 1 SHOWING THE CAM ARRANGEMENT.

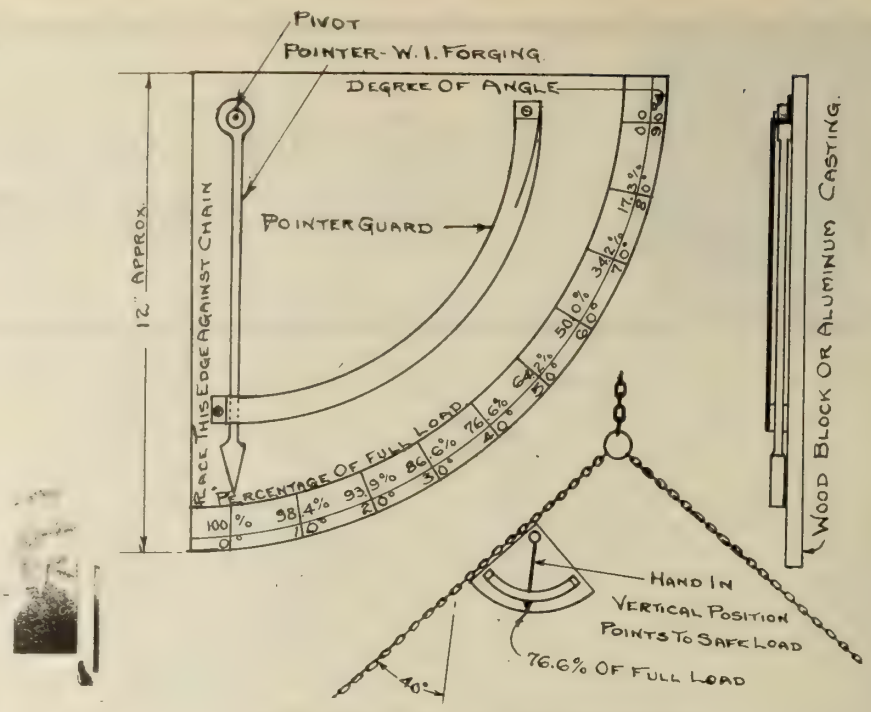
clamped in a circular grinding fixture, shown in the upper left of Fig. 1. The template is located over the clamping washer and turned in either direction until the outline exposes a minimum of margin on the casting. The outline is scribed on the cam, the template removed and the excess of metal ground away on a large size grinding machine of the Besley type. For this purpose the rocking table is clamped and the fixture is rotated and fed slowly, by hand, until the ground edge "splits the pops." The contour is then finished with a smooth file. The template and fixture is common to all cams.

By means of this adjustable template it may well be that all cams are not identical, point for point, but regarding the radius of the curve, they will have the same rise per degree, therefore the four cutters will have exactly the same feed from similar parts of their respective cams.



## CHAIN CAPACITY INDICATOR

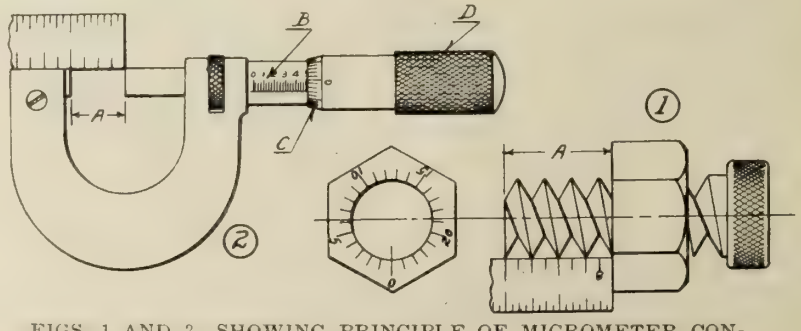
By M. C. ALLIN

The instrument shown in the illustration will be found very useful where the handling of heavy machinery is involved, such as long planer and lathe beds or any long articles which require to be held at both ends when lifted by an overhead travelling crane. The hoisting chains in these cases are necessarily set at a fairly large angle to the vertical, thus reducing the load carrying capacity of the chain to a considerable extent.

This instrument will instantly show the safe carrying capacity of the chain, no matter what angle to the vertical it may be resting at. The instrument is shown graduated in percentages of full load but may be specially graduated in pounds to suit any particular chain or rope.

It may be made of any suitable light material such as aluminum, hardwood with sheet brass graduated scale, etc. The pointer should be freely suspended and heavy enough at the lower end to cause it to keep a vertical position whenever the frame of the instrument is placed against the chain. The pointer will then indicate the percentage of the full load the chain will carry when hoisting a heavy weight, the chain being at any angle to the vertical as fixed by the shape of the object to be lifted. This method of quickly checking the safe carrying capacity of a chain should help produce safe loading and prevent unnecessary accidents.

DETAILED VIEW OF THE INDICATOR.



## PRINCIPLE OF THE MICROMETER

By F. M.

The idea here given is by no means new, but will probably be interesting to many readers. Fig. 1 illustrates a screw and nut adapted to explain the principle of the micrometer. The face of the nut is graduated into 25 equal divisions, and as the screw has four threads per inch, one revolution of the nut will move the same ¼ inch, or .250 of an inch, the 25 graduations on the end indicating various portions of a revolution; therefore, taking any fraction of a revolution and noting its relation to the zero line and dividing into .250, the result is the number of thousandths movement of the scale if kept in contact with the nut. For instance, if 5 was on the zero line the movement would be .250 divided by 5 equals .050 inch. The principle in the micrometer is identical with the exception that the screw has 40 threads per inch. Referring to Fig. 2 the barrel of the micrometer has 25 graduations at C, and it requires 10 revolutions of the thimble to move it .250 inch. Reading any of the lines at B in multiples of 25, together with the indicated reading at C gives the micrometer calibration at A. This simple method of instruction will be of great assistance to instructors of apprentices and machine operators in explaining the operations of the micrometer caliper.

## REORGANIZATION SCHEME.

A scheme for the reorganization of the Oakoal company (Canada), limited, in liquidation, has been placed before the master-in-ordinary at Osgoode Hall, by A. C. Master, counsel for the shareholders. The plan is to form a new company, with nominal capital of $400,000, divided into 400,000 common share. Each holder of fully paid preference and common shares in the present company would be entitled to five common shares in the new company, with 75 cents credited as being paid on each share. Provisional directors in the new company are: Douglas Cooper, H. J. Birkett, W. T. Pember, W. R. Jackson, all of Toronto, and R. W. Dixon, Oshawa.

# WELDING AND CUTTING

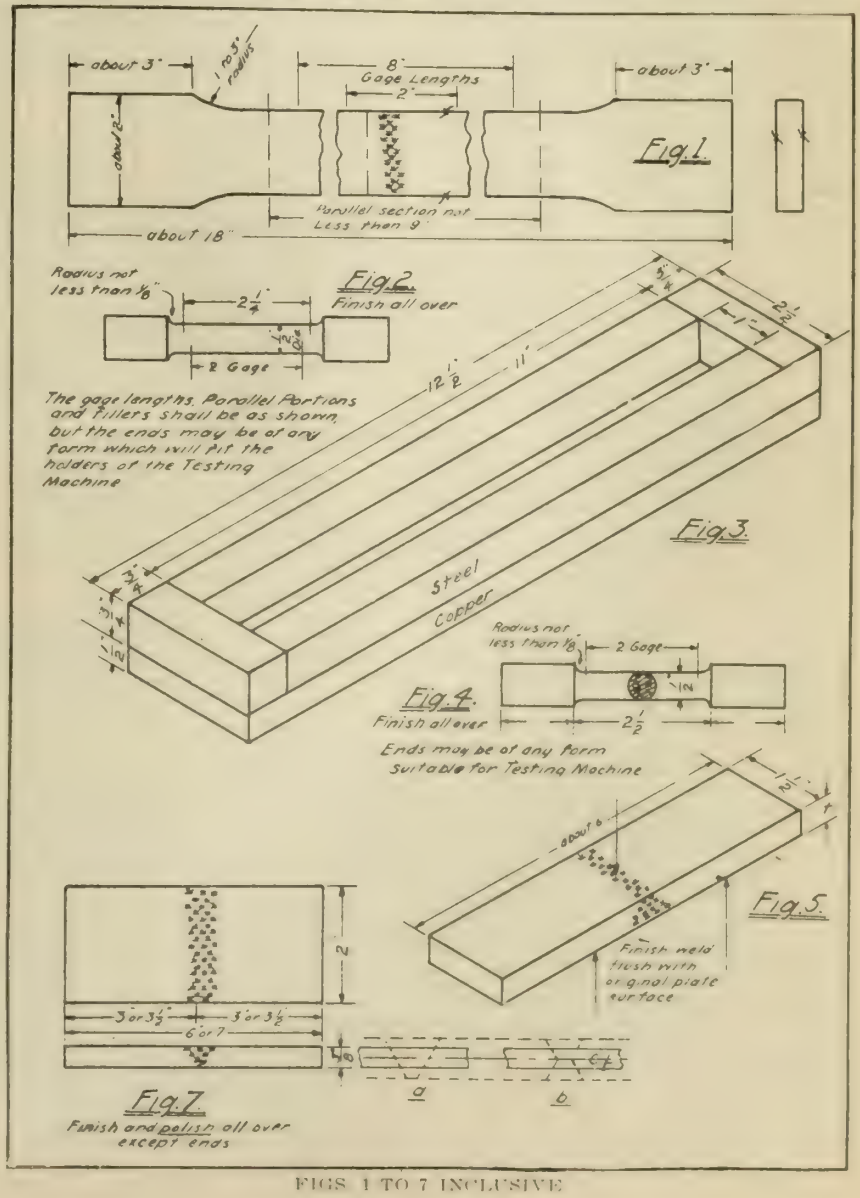
# Have You A Standard Method for Testing Welds?

## These Specifications, Prepared By The American Bureau of Welding Are Intended To Serve As A Standard Basis for Testing And Comparing Sample Welds As Distinguished From Welds In Structures

THE welding industry in general will no doubt welcome the specifications for standard tests of welds, recently issued by the American Bureau of Welding. As C. A. Adams, the director of the Bureau states:

"We are submitting herewith specifications for Standard Tests of Welds. Standardization of the procedure in making a test of any kind is obviously necessary before results obtained by different observers can be compared. The chief difference between testing a specimen of steel that includes a welded joint and testing an ordinary specimen is the non-homogeniety of the welded specimen. The welded specimen has its center, a section composed of material that usually has physical, chemical and metallurgical characteristics distinctly different from the adjoining metal. Furthermore, the section of the added metal is more or less irregular in shape and variable in size. Consequently the procedure prescribed for testing of ordinary specimens is not applicable to specimens containing welded joints.

Differences in details of procedure have caused widely divergent results that comparisons are frequently impossible, with the results that the usefulness of much of the research work on record is generally restricted and in many cases the results are actually misleading.



Although more thorough research work in this field may develop more satisfactory standards for tests of welds, the need for some immediate standards is so great that the universal use of the accompanying specifications is urged upon all those who have to do with the testing work in this field. Criticisms and suggestions are invited. The present standards will be valid for a period of one year and at the end of this period they will be modified if it is found desirable.

**Report to the Bureau of Welding of the Committee on Standard Tests for Welds.**

The committee held a meeting on February 3, 1921, at the Engineering Building, New York. After some discussion of its two fields of activity, namely preparation of standards for comparing welds and standardization of tests to be applied to welds in finished structures, it was concluded that (a) the committee should first work on standards for comparing welds and (b) the material prepared by a similar committee under the Welding Research Committee of the Emergency Fleet Corporation, which was the result of a great deal of work on the part of several men, should be utilized as fully as possible.

The committee in preparing the "Standards for Testing Welds," which are transmitted herewith, proceeded on three assumptions as follows:

1. The fundamental basis of measuring the effectiveness of a joint between two pieces of metal is the best metal without a joint. A joint is a necessary evil in a structure which is avoided when it is possible. Therefore the value of a joint is best determined by comparing the characteristics of a section of the structure which includes the joint with those of a similar section which has no joint. In other words, a

FIGS. 1 TO 7 INCLUSIVE

work is a joint and the practical basis of evaluating a weld is in terms of the metal of the parts joined together.

2.—Three standards are desirable as follows:

(a) **Shop Standard.** In the shop a standard test is required for such purposes as checking the work of a welder from time to time, testing a new lot of electrodes in electric welding or of welding wire in gas welding, testing the effect of some change in conditions which may have taken place, et cetera. Such a standard must necessarily be as simple as possible and preferably a single test. The technique of the procedure in making the test must be of a simple character.

(b) **Commercial Standard.** There are many cases where more than one test or test should be made, but where the circumstances do not justify a complete investigation. There is, therefore, a need for what might be termed a commercial standard for making, for example, comparisons between different commercial welding processes or between different kinds of electrodes in electric metal-arc welding or different wires in gas welding.

(c) **Research Standard.** When a complete investigation of a weld is to be made for research or other purposes, all tests and examinations are made which will contribute any information in regard to the characteristics of the weld. It may be necessary to make tests of a special character in special kinds of welds or where application under unusual conditions is contemplated, but there should be a standard list of tests which will give information which is complete as far as all ordinary requirements are concerned.

3. The details of the procedure in making the various mechanical tests should be carefully prescribed. It is believed by the committee that standardization in this respect is of the greatest importance because comparatively small differences in procedure have a marked influence in certain mechanical tests and unless these are eliminated the results are not comparable.

The committee recommends that the proposed "Standards for Testing Welds" be adopted, at least tentatively, and be offered by the bureau for general use. It may very well be that experience will show the desirability of making changes but that can only be determined after the standards are in use. Respectfully submitted, W. J. Beck, S. W. Miller, R. E. Wagner, H. L. Whittemore, F. M. Farmer, Chairman.

### Standards for Testing Welds.

Note: These specifications are intended primarily to serve as a standard, uniform basis for testing and comparing ample welds as distinguished from welds in structures. The testing of the latter must necessarily be by non-destructive methods which would therefore be, in general, quite different from those employed in examining sample welds (test welds) made, for example, for the purpose of testing a welder's proficiency, comparing welding wires or comparing welding methods.

### Definitions.

The following are definitions of terms employed in this specification.

(a) A Weld is a solid union of metallic pieces formed by uniting or consolidating by hammering or compressing with or without previous softening by heat.

Note: This definition is quoted from the Century dictionary. It is the broad definition of a weld and therefore includes forge welding and resistance welding by either the butt or spot process. While these specifications are prepared specifically for fusion welds, it is obvious that some of the tests can be applied to other types of welds.

(b) A fusion weld is a weld formed by heating to a fluid state the edges of the pieces to be joined and allowing the metals to flow together (with or without additional molten metal being supplied) wthout any pressure being applied. The heat may be supplied by a gas flame, an electric arc thermit or otherwise.

(c) In a fusion weld, the base metal is the material composing the pieces to be united by the weld. Unless otherwise expressly stated, it will be understood that a weld joins two pieces of identical material.

(d) In a fusion weld, the weld metal is the material which has been used in forming the weld. It may consist entirely of a base metal adjacent to the weld or of the material added to the fused base metal from a welding rod or electrode, or other material.

(e) Filling metal is the metal added during the welding process to form part of the weld. In gas welding it is supplied by means of a welding rod, in carbon arc by filling rod and in metal arc welding by the electrode.

(f) A test weld refers to a sample of welding which has been performed under known conditions and upon which mechanical tests are to be made.

(g) A test specimen is a prepared piece on which a mechanical test is to be made.

### Shop Standard.

Bending test only.

### Commercial Standard

(a) Bending test.
(b) Tensile test.

Note: It is probable that eventually it will be desirable to include a fatigue test when a method is standardized which will be suitable for commercial application.

### Research Standard.

**A. Tests of Base or Parent Metal.**

1. Chemical analysis. To include carbon, manganese, silicon, phosphorus and sulphur.
2. Mechanical Test.
   (a) Tensile. To include yield point, ultimate strength, total elongation and reduction of area.
   (b) Bending.
   (c) Fatigue.
3. Metallographic. Photomicrographs at 100 diameters.

**B. Test of Weld.**

1. Mechanical Test.
   (a) Tensile. To include yield point, ultimate strength, total elongation and reduction of area.
   (b) Bending.
   (c) Fatigue.
   (d) Impact.
2. Metallographic. Photomicrographs at 100 and 500 diameters respectively at (a) the junction between the base metal, and the filled-in metal, (b) the base metal adjacent to the junction, (c) the center of the filled-in metal.

**C. Test of Filled-in Metal.**

1. Chemical analysis. To include carbon, manganese, silicon, phosphorus and sulphur.
2. Mechanical tests. Standard round specimen to be prepared from ingots deposited in a base-metal mould of such dimensions that normal cooling conditions will be approximated.
   (a) Tensile. To include yield point, ultimate strength, total elongation and reduction of area.
   (b) Bending.
   (c) Fatigue.
3. Metallographic. Photomicrographs at 100 and 500 diameters respectively.

### Standard Procedures for Mechanical Tests.

**1. Preparation of Test Welds.**

No detailed instructions for the preparation of test welds can be given as the dimensions, material, etc., will depend upon the purpose for which the weld is being made. The test weld should, however, duplicate as nearly as practicable the commercial welds which it represents and should preferably be of such a size as to permit preparations of enough specimens from the one test weld to make all of the mechanical tests which are to be made.

When the test weld is made with material in sheet or plate form, the longest axis of the test specimen should, in general, be parallel to the direction of rolling.

**2. General Procedure.**

(a) Wherever applicable, the standard procedure of the American Society for Testing Materials as given in the A.S.T.M. for 1918 (serial designation E-1-18) shall be followed.

(b) Three duplicate specimens shall be tested in any one test and the average taken as the value of the property determined by this test.

**3. Tensile Tests—Base Metal.**

**(A) Test Specimens.**

(a) **Sheet or Plate Material.** The test specimen for sheet materials is shown in Fig. 1. The thickness of the specimen may be any that is desired, but a thickness exceeding ¾-inch would require a testing machine in excess of 100,000-pound capacity. If the specimen is cut from standard sheet material, it is usually not necessary to machine the 1.5 inch faces of the specimen.

(b) **Cast Material.** The test specimen for cast or brittle materials is indicated in Fig. 2*. It is particularly important to use swivel specimen holders when testing such specimens in order to entirely eliminate undesirable stresses.

**(B) Test Results to be Recorded.**

(a) **Ultimate Strength.** Unit stress (lb. per sq. in.) computed from the area of the original section.

(b) **Yield Point.** Unit stress (lb. per sq. in.) at which marked increase in deformation of the specimen occurs without increase of load as indicated by a sudden dropping of the beam of the testing machine or by a sudden increase of the rate of elongation as shown by dividers.

(c) **Contraction of Area.** Expressed in per cent. of the original area.

(d) **Appearance of Fracture.** The appearance of the fracture as determined with the aid of a low power magnifying glass (such as jewelers use) should be recorded. The characteristics described by the following nomenclature should be covered indicating as far as possible the per cent. of the total area which is involved. For example, "10 per cent. not welded" would signify that approximately 10 per cent. of the total area of cross section at the fracture is exposed base metal—that is, not welded.

Spongy: Full of small cavities; the structure resembles that of a sponge; porous.

Slag inclusions: Foreign matter entrapped in the weld.

Gas pockets: Small or large cavities more or less isolated (i.e., not of a regular spongy structure).

*The diameter of this specimen may be 0.505 inch if desired. This diameter gives an area of exactly 0.200 square inch.

Not welded: Exposure of any portion of the surface of the base metal indicating imperfect fusion between the base metal and the filling metal.

Laps: Imperfect fusion between adjacent portions or between successive layers of filling metal.

(The recording of the following data is optional.)

(e) **Proportionately Limit.** Unit stress (lb. per sq. in.) at which the deformation ceases to be directly proportional to the load.

Any type of extensometer may be used but in precise work the deformations of two opposite elements of the specimen, preferably on the edges, should be obtained. For ordinary purposes deformations in only one element of the specimen need be measured, but in that case the gauge marks should be on the center of the line of the 1.5-inch side.

The gauge length may be either 2 or 8 inches.

(f) **Modulus of Elasticity.** Unit stress (lb. per sq. in.) computed from data obtained from a specimen having an 8-inch gauge length; measurements to be taken on two opposite elements, one on each edge of the specimen.

(g) **Total Elongation.** Gauge marks shall be laid off every inch along a line at the center of one of the 1.5-inch faces of the specimen before placing in the testing machine and the total elongation in every inch after rupture recorded. The total elongation in the 1-inch, 2-inch and 8-inch (if any) length which included the break shall be reported.

**4. Tensile Tests, Weld Metal.**

**(A) Test Specimens.**

The shape and dimensions of the test specimens are shown in Fig. 2. It shall be prepared from a bar of weld metal, ¾ by 1 by 11 inches. This bar shall be formed entirely by depositing filling metal in an open box of the shape shown in Fig. 3, employing exactly the same method used in making the corresponding test weld. For metal electrodes this box shall consist of a copper plate ½-inch thick, upon which is secured a frame of steel bars, ¾-inch square. The parts of the box were secured in any convenient manner. The copper plate, during this operation shall rest upon a steel plate. After the bar is formed, the copper plate and the frame may be removed by any suitable machining operation.

For gas welding, the copper plate should be replaced by a steel plate. For thermit, a box of suitable refractory material should be used.

**(B) Test Results to be Recorded.**

These shall be the same as those prescribed in Section V, 3-B (base metal) except those involving an 8-inch gauge length. If, however, the modulus of elasticity is desired, a specimen similar to that shown in Fig. 2, with a gauge length of 8in. shall be employed.

**5. Tensile Tests, Weld.**

**(A) Test Specimens.**

The shape and dimensions of the test specimen are shown in Fig. 1 with the weld at the center. If the material is cast or brittle, the specimen shown in Fig. 2 shall be used with the weld located at the center.

It is especially necessary that the 1.5 inch sides of the specimens be machined, particularly if the two pieces of base metal are offset or if they form an angle at the weld. Tests made in the latter case, where the specimens are not machined, are not reliable. Furthermore, care must be taken that specimens having the latter defects are not "straightened" before being machined because such treatment is likely to materially decrease the strength of the weld. A roughening cut in a planer or shaper which will just "close up" the surfaces of the specimen is sufficient.

**(B) Tests Results to be Recorded.**

The requirements for test results given in Section V, 3-B (base metal) shall be followed.

**6. Bending Tests, Base Metal, Weld Metal and Weld.**

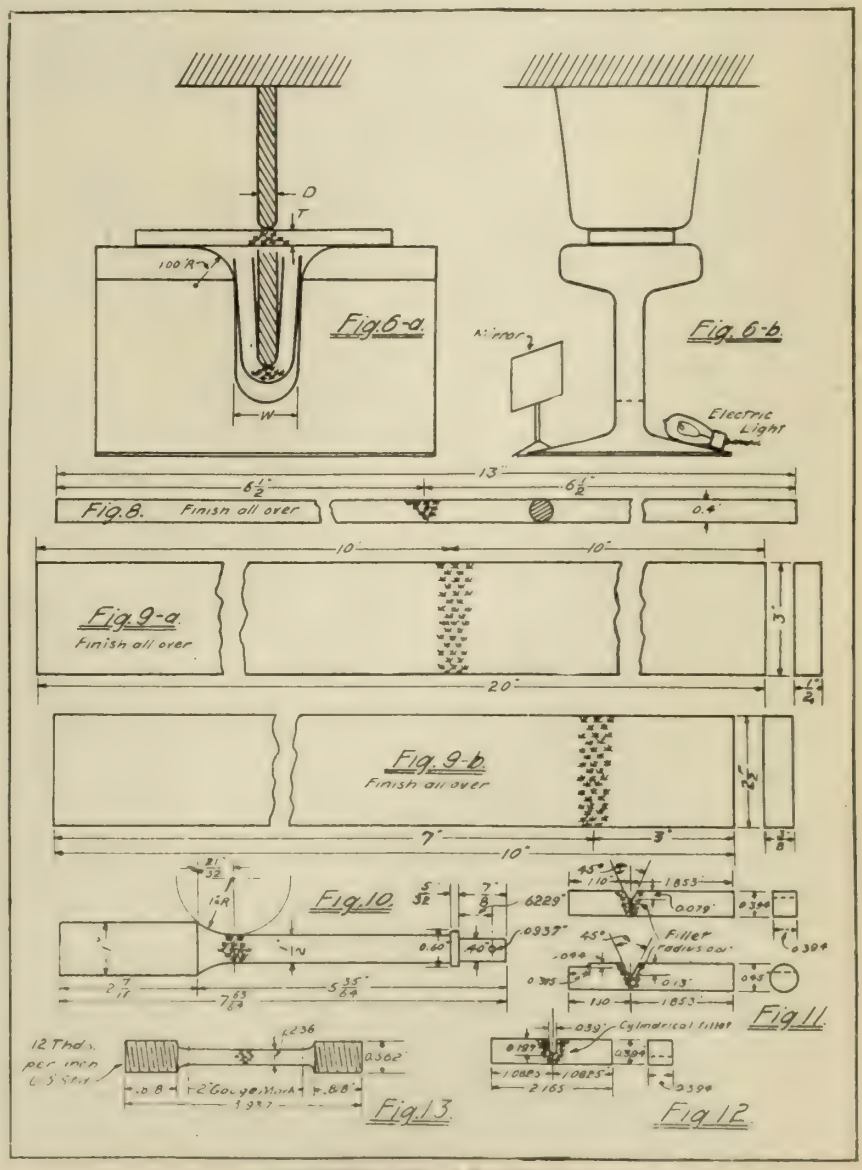
**(A) Test Specimens.**

(a) **Base Metal and Weld.** The shape and dimensions of the specimen are shown in Fig. 5.

In the case of welds in flat rolled material, the surface of the weld shall be machined substantially flush with the surface of the specimen unless the specimen is bent or offset, in which it shall be machined all over. Cast and other irregular specimens shall be machined all over. It is essential that the edges of all specimens be machined to remove material in a condition likely to cause premature failure.

The thickness, t, of a weld specimen shall be as nearly that of the base metal as possible.

(b) **Weld Metal.** A specimen may be prepared from a bar of weld metal prepared as prescribed for tensile tests (Section V, 4-A). The box, Fig. 3, shall however have a width of 1.75 inches and the thickness, t, of the specimen shall be that of the test weld. These specimens shall be machined all over.



**(B) Apparatus.**

In order to load the specimens so that as large a part of the bend as possible shall occur in the weld metal, the special fixture outlined in Fig. 6a and 6b shall be used. It is most conveniently used with any standard universal testing machine but may be operated by any other convenient mechanical means.

The cylindrical surface, D, (Fig. 6a) about which the specimen is bent shall conform to the requirements of the American Society for Testing Materials for bending tests of the base metal. This piece is attached to the under side of the moving head of the testing machine. Upon the platform shall be fastened two blocks having machined top surfaces and polished corners of radius, R, of 1.00 inch. These blocks shall be separated by a distance, W, equal to D plus 2T plus ⅛ inch. A lubricant of lard oil and graphite or similar compound shall be used on these surfaces.

Two specimens shall be tested. The load shall be applied at the center of the weld,—in one specimen to the open side of the "V" and in the other specimen to the closed side.

The rate of application of the load shall not exceed that at which the beam can be kept balanced at all times or a maximum of 2 inches per minute.

SHOWING FIG. 6 TO FIG. 12

the specimen which is reversed during each revolution of the machine.

Specimen shown in Fig. 7. The distance between the jaws of the machine shall be ½ inch. If the specimen is a weld specimen, the jaws shall be equidistant from the center of the weld metal.

(c) **Farmer Machine.** This machine was designed specially for testing weld specimens. It tests the specimen as a simple rotating beam with free supports at the ends and two equal loads on a section at the middle. Specimen shown in Fig. 8. If the specimen is a weld specimen, the weld metal shall be at the center.

(d) **Strohmenger Reverse Torsional Machine.** Comparative results only can be obtained as there is no means of determining the stress. This machine loads the specimen in torsion which is reversed for each revolution of the machine.

Specimen shown in Fig. 9a.

(e) **Strohmenger Bending and Impact Machine.** Comparative results only. The machine strikes the specimen which is held as a cantilever beam, bends it and releases it. This operation is repeated upon the other side of the machine. The weld, if any, is placed just outside the clamp in such a position as to develop the maximum stress in the specimen.

The specimen is shown in Fig. 9b.

(f) **Moore Machine.** This machine was designed for the Bureau of Standards for testing large size specimens of joints, both welded and riveted. It loads the specimen as a simple beam at the third point and the direction of loading is reversed for each revolution of the machine.

Specimens. Any thickness not exceeding about 1 inch, width 8 inches, length 32 inches. If the specimen is a weld specimen, the weld metal shall be at the middle of the length of the specimen.

(g) **White-Souther Machine.** This machine loads each end of a rotating specimen as a cantilever beam. It is then rotated.

The specimen is shown in Fig. 10.

**(B) Test Results to be Recorded.**

(a) Number of cycles of the stress required to cause failure. A cycle is the period of time at the end of which the repetition of the variations of stress is begun.

(b) The stress developed in the specimen (if possible).

## INSPECTING CLOSED BOXES BY X-RAYS.

X-rays are a form of light which has the power of penetrating substances which are opaque to ordinary light. The more dense the substance the less it is penetrated, so that the rays falling on a composite body, such as a box with metal nails and hinges, throws a kind of shadow picture of the hidden parts on a photographic screen. This fact has been utilized in the examination of manufactured articles. Recently a British Government Department brought out a portable X-ray outfit for examining large numbers of boxes, without opening them, in order to see whether they contained all the essential parts. The apparatus is placed on wheels and is solidly built to stand rough use in the workshop. In place of a photographic plate a fluorescent screen is used so that the operator can actually see the shadow picture thrown by the contents of the boxes. By the use of this equipment an immense amount of time has been saved in the inspection of thousands of articles.

## THE NAMING OF PIPE.

When should we use the term "Wrought Pipe?" Here is how "Mechanical Engineering" solves the question:—

Whether the pipe-maker takes a length of steel skelp or a length of wrought-iron skelp and forms it into a pipe, he performs exactly the same operation in either case, that is, he bends the skelp into tubular shape and welds the edges. Quite correctly, therefore, the American Society for Testing Materials in its specifications uses the word "welded" in reference to both wrought-iron and steel pipe made by the welding process.

Probably some thirty years ago, after the introduction of welded steel pipe, the term "wrought pipe" or "wrought steel pipe" was coined by steel-pipe manufacturers. This term gradually came into use by dealers and jobbers; thus steel pipe would be billed and listed as "wrought pipe." Many purchasers of pipe, not being acquainted with this trade name, frequently labor under the impression that it means wrought-iron pipe.

The manufacturers of wrought-iron pipe, actively aided by the American Institute of Architects, have therefore taken up with the supply associations the matter of clarifying these so-called trade names, suggesting instead names that would ultimately result in eliminating all confusion of pipe made from puddled wrought iron with that made from soft steel. As a result the National Pipe and Supplies Association at a recent meeting voted that the terms employed by the American Society for Testing Materials in differentiating between iron and steel pipe, namely, (1) welded wrought-iron pipe, and (2) welded steel pipe, should be accepted and adhered to by the distributors of both iron and steel pipe.

This step should result in the term "welded pipe" being applied when both wrought-iron and steel pipe are referred to, and in the latter two terms alone, namely, "wrought-iron pipe" on the one hand and "steel pipe" on the other hand, being used and interpreted, respectively, to mean exactly what these terms imply. Thus "wrought-iron pipe" will mean only pipe which is made from genuine puddled wrought iron, and "steel pipe" will be used exclusively to designate pipe made of soft bessemer or open-hearth steel.

## STETHOSCOPE IN WORKSHOPS.

Most of us are unfortunately, more or less familiar with the stethoscope, which the doctor uses when listening for the signs of defective action in our lungs or heart. It is not so widely known that the same kind of instrument can be employed to detect abnormal noises in moving machinery. The latest development in this workshop stethoscope, due to a British engineer, lies in the use of a kind of telephone receiver in place of the stethoscope rod. The advantage of this device is that every bearing and every gear in a factory can be fitted permanently with a receiver and all the receivers can be connected by electric wires to a single board in the manager's office or any other convenient spot. By means of suitable switches the manager can examine each bearing or gear in succession without moving from the board. Since abnormal internal noise is often the first sign of trouble which may lead to breakdown this simple and rapid means of detection is an invaluable aid to the factory owner.

## Seven Successful Rules for Selling

CONSIDERABLE experience can be gained in a space of 45 years, especially in the selling end of a business. H. Hamlin Childs, in a recent issue of "System," brings this home very forcibly in an article entitled "What 45 Years in Business Have Taught Me About Selling." Among the many valuable suggestions contained in this article are seven selling principles that experience has proved to be not only satisfactory, but efficient in working qualities. Mr. Childs comments as follows:

1. "The business that merely offers its product for sale will never get anywhere. Everything has to be positively sold.

2. "Energy devoted to fighting a competitor is apt to be a wasted energy. A more satisfactory return will be had by forcing one's own affairs forward.

3. "One of the easiest ways to draw attention to the fact that one's product is best, is to charge a higher price than competitors charge.

4. "Above all, it is not possible for even a month to let up on the advertising pressure. That must be continuous.

5. "No one will buy from you simply because you want to sell. People will buy from you only because you have something that will do them good in proportion to the price you charge.

6. "It is extremely difficult, as a business grows, to avoid a public expression of satisfaction in the growth—and to remember the public is interested only in superiority of service.

7. "The value to my mind of the various trade-marks that we have established and the reputation of the company itself, which has been trade-marked by a distinctive signature, is greater in actual business value than all the material assets we carry on our books."

## Hot Oil as Hardening Medium

SPEAKING on "Hardening in Hot Oil," H. E. Twigg, in a recent issue of American Machinist, tells a humorous story of a foreman who wanted some information as to why hot whale oil hardens steel harder than when it is cold. He mentions that this foreman always prepared his oil bath for hardening cast steel cutters by getting a small die red hot and plunging it into the oil to warm the oil preparatory to hardening.

The author continues:

When another foreman was recommended to try this he ridiculed the suggestion, expressing the futility of it. He instanced the provision of circulating water to keep oil cool in the hardening bath by those who know all about such things. He was asked to try it nevertheless, and I suppose he did as he could not be induced to make any further remarks upon the subject although repeatedly asked to do so.

I may say that some time ago I hardened about 30 cutters 2 in. in diameter by ⅞ in. thick. The quenching tank held about two or three pints of oil and the cutters were quenched singly. The last one quenched made the oil so hot that it boiled over and left the previously hardened cutters bare. I went over them all with a file to test them, thinking I had gone too far, but found that they were "all right."

I can quite understand that the boiling point of whale oil is considerably less than that of linseed or tempering oil, but I should like to know the reason for hot oil hardening better than cold oil. It may be because it is more fluid; at any rate some of your hardening experts probably could enlarge upon this subject. My father, who had some knowledge of the steel button trade in the early fifties told me that he had heard a hardener remark that the oil hardened better at the end of the day when it had become well warmed up.

Our cutters are now heated by natural draft gas furnaces and quenched in hot or warm water, but I should imagine that on the question of warping, or on tricky work, hot oil would be better. I may add that in my first experience of using linseed oil for tempering springs, during which more heat was wanted and more coal was put on the fire, the oil boiled over until the flames nearly reached the ceiling. The top of the thermometer was blown off, though this was not noticed until later. Why the thermometer broke I did not understand, particularly as the maker subsequently informed me that mercury boiled at 620—but I expect he is wiser now as this happened thirty years ago.

## Centrifugal Casting Process

A process for the centrifugal casting of pipe has been patented by L. Cammen, New York. The process as described in "Iron Age," is carried out in four stages.

The metal is first melted and cast into bars, which when solidified are weighed, cut off to exactly proper weight, and while still hot are transferred to a pipe mould. This mould has an outside steel shell ½ in. to 1 in. thick, to give mechanical strength and act as container. Inside of this is a lining made up of hard-baked clay-rings, ¾ in. to 4 in. thick and 2 in. to 3 in. long. Inside of these is a graphite lining made up of tubes ¼ in. to 1 in. thick and 18 in. to 24 in. long. The mould is closed at both ends by graphite blocks, terminating in copper insulated leads.

The moulds are placed on a rack and electric current is supplied to the terminals from a bus-bar. They are left on the racks until the metal inside has thoroughly melted, which of course is determined by the strength of the current and the time elapsed. The moulds are then transferred to the spinning machine. The speed at which the moulds are spun is determined primarily by the diameter of the tube to be cast and the thickness of the wall. Spinning continues until the metal has solidified, the time varying according to the kind of metal and to a certain extent on the initial temperature of the metal; 60 to 90 sec. appear to be ample. When the metal in the tube has set, it is allowed to cool until the contraction of the diameter of the tube is sufficient to pull it out of the mould. It is then subjected to such heat treatment as may be necessary.

The advantages reported for the process are control of composition of the metal of the tube, absence of gases in the mould, also the production of wrought-iron pipe, chromium tubing, Monel-metal tubing, and even high-speed steel pipe for use in modern high-pressure high-superheated steam for power plants.

## The Care of Ropes

IN ordinary use ropes have not a very long life if safety in sustaining heavy strains is considered; but, provided they can be kept dry, the decay is chiefly caused by the breakage of fibres, machine-made ropes being less durable than hand-made ones of equal diameter and weight. Of course, a machine-made rope laid up with close and short coils of strands looks better than the more loosely laid up hand-made rope, but under a heavy strain the machine-made article breaks up quicker owing to the disposition of the fibres which are under greater initial tension, and it will be found that dressings do not really much alter this, although they do not increase the strength of the ropes at any time. For working purposes, continues Practical Engineer, a tarred or otherwise dressed rope maye be taken at approximately a third less power in a direct pull owing to the fibres sliding over each other instead of gripping firmly; but as few persons put the fullest load on a rope, this does not seriously affect working as a general thing, and it may be taken that while a good rope of 1 in. diameter will, when new, lift a ton safely, a tarred rope of equal size will not be altogether safe with a load of more than about 13 cwt. Fibre—not coir—ropes appear to be best steam-dressed with Stockholm tar, but other things are used to suit the ideas and prices of different persons; in all cases, however, the object of the dressing being to prevent damage from moisture.

# DEVELOPMENTS IN SHOP EQUIPMENT

### SIMPLIFIED MOTOR DRIVE.

The Dreses Machine Tool Co. Cincinnati, Ohio, have recently brought out a simplified design of motor drive for radial drills.

A pinion on the motor meshes directly with a large gear on the horizontal back shaft of the arm, this eliminating two pairs of bevel gears, three spur gears, eight bearings and two long and one short shaft in the driving mechanism. This simplification is said to permit the using of a motor of one-third less capacity than if placed at the base of the drill.

The controller is placed in front of the motor and the controlling handwheel brought within easy reach of the operator by means of a universal joint, shaft and bracket. The hand wheel rim is beveled and marked to show the spindle revolutions at the different stations of the controller. A fixed pointer reaching over the hand wheel serves as an indicator. This arrangement eliminates several parts that are necessary when the controller is placed in the rear of the motor and arm.

The motor is placed on a sub-base so that any make may be used without making a change in the arm.

### DRILLING MACHINES.

The Cincinnati Hy-Speed Machine Co., Cincinnati, Ohio, have placed on the market a line of drilling machines to be known under the name of Hy-Speed. Various features are claimed for these machines, among them being the single-pulley, direct, overhead drive and the dry-plate clutch operating in connection with the externally clamping, adjustable, air-cooled brake. By means of a single handle directly in front of the operator, the machine can be instantly started and stopped, adding considerable speed and convenience to the operation of the machine.

The elevating mechanism of the table is so arranged as to allow drills and taps to pass through the center of the table. This construction, combined with the use of the quick-releasing chuck, allows tapping without reversal. The spindle speeds are controlled by a handle on the side of the column. An automatic power feed and an automatic tapping attachment can be arranged on any spindle. Unit construction is embodied in the machine. The entire clutch, brake and the initial driving gear form a separate unit that is set into the top bracket of the machine.

The machine is built in various types for either floor or bench use, with a single speed if desired, or a belted motor drive, an automatic power feed or an automatic tapping attachment.

### CUTMETER.

O. Zernickon, New York, N.Y., have placed a device on the market called the O-Z Cutmeter. This tools is intended for determining the cutting speed of machine tools of all types. It may also be used for such purposes as ascertaining the speed of rolls in paper mills and the linear speed of belts and ropes.

When in operation the device is held by means of the handle, and a small wheel is placed in contact with the moving works or machine table, the surface speed being shown directly on the dial. The meter operates on the governor principle, and it is said that its accuracy is not affected by changes in temperature, by moisture or by the presence of magnetic fields. A damping mechanism is incorporated, so as to prevent vibration of the indicating hand, the mechanism serving to neutralize shocks and vibration which would be transmitted from the machine or work being tested. When fitted with the pointer provided for the purpose, the device may be used to indicate revolutions per minute. It is not necessary to use a watch to time the period of test, nor to calculate the speed. The device is said to operate equally well in any position. By means of the three separate ranges, the device may be used to indicate revolutions per minute from 30 to 1,200 and speeds in feet per minute from 20 to 800.

### RAPID STONE-CUTTER.

Machines for cutting marble and other stone have a pedigree stretching back to very early days in civilization, and they still often bear the marks of their primitive ancestry. Recently, however, a British engineering firm introduced a type which more closely resembles a machine tool than the crude equipments with which our forefathers were content. It is intended mainly for cutting and moulding but it may be used also for slab and block work. The stone to be cut is placed on a table surmounted by a saddle carrying a carborundum wheel or a "diamond saw," which runs at 1,200 revolutions per minute and is kept cool by streams of water. A diamond saw is built up by arranging individual diamonds in metal "saddles" on the rim of a disc. Each saddle is drilled from behind, the diamond inserted in the hole and electrically welded over, and then mounted on the rim. The metal covering the diamond is ground away leaving the diamond exposed. Wheels of this type make very rapid and efficient cutters of stone and the use of the machine is expected to lead to remarkable economies over the older methods.

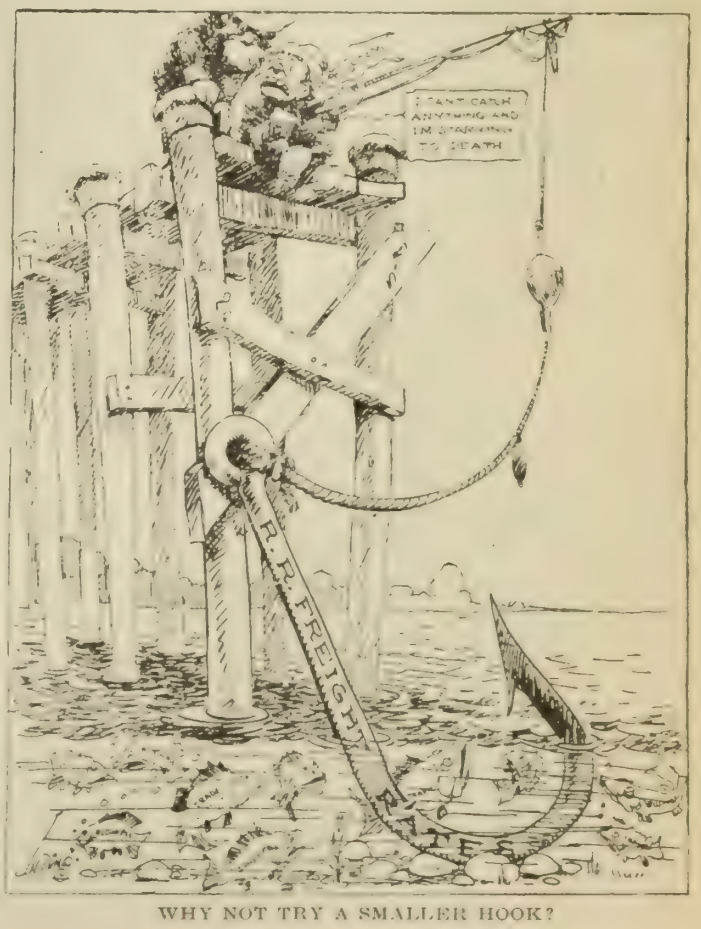
## Canada and Export Trade

THE visits of Sir John Hendrie and Sir Edmund Walker closely following each other, led to comments strikingly similar in character from both gentlemen. They each point out that under certain conditions there can be worked up a reasonable export trade to this part of the world, but point out very strongly that the manufacturer who wishes to get a share of this trade must live up to the rules, and play the game squarely.

The buyer in Latin America is usually a man of great discrimination, and as far as articles in domestic use are concerned, a very much more critical buyer than his contemporary in North America. This is due to his inherent tastes, and his long intimacy with the best that Europe can produce. The best that Europe can produce is a great deal ahead of the best that can be produced in Canada, although perhaps it may be treason to suggest such a thing. Therefore, the goods that are to be sold must be honestly described, and the goods themselves must live up to their description and sample where there are samples used. Smart tricks of business, or in other words sharp practice will not get a firm or an individual very far in dealing with these people, or any other, and the statement is made that there are millions of dollars worth of goods lying on the wharves of South American ports, rejected because of not coming up to the sample they were sold on.



The English manufacturer and merchant, who has been engaged in export trade since the days that there was such a thing, holds his markets by the excellency of his products, and a strict honesty that has made him famous all over the world. That reputation has been built up by a scrupulous integrity in all his dealings, and when a competing nation goes out to capture a foreign market, they have that reputation to live up to. On this continent it is a fact that strict probity in business is not considered essential, so long as a little sharp dealing can be got away with. The fact is recognized by all parties, and the attitude is taken that one must be smart enough to avoid being caught. In dealing with buyers in overseas market that attitude must be forgotten, and the fact borne in mind, that if only because it pays best, honesty is the best policy.

## Have You a Cost System?

"WHAT does your product cost?" Sounds like a reasonable queston, and yet, how many manufacturers could give an intelligent answer. Cost accounting, unfortunately, is something that has been too little understood to be generally used. Up to a short time ago, everybody was turning down orders rather than looking for them. Prices were high, in fact there was almost no limit to the prices one could demand, so naturally the cost of a product was a minor consideration. The manufacturer was more interested in getting out the goods, rather than keeping tab on his costs. His profits were large, so why worry about the cost of production. This, briefly, was the state of affairs previous to the present inactivity.

But now the situation is reversed. Instead of turning down orders, the manufacturer is looking for some order of decent proportions. Prices are no longer sky high, and if a firm wishes to secure an order they must first submit a reasonable price. The man who overbids through overestimating the cost of his production seldom gets orders. The fellow who underbids loses so much money in a short time that he cannot remain in business.

This condition leads us to suggest that now, if ever, is the best time to seriously tackle the subject of costs. We do not suggest you install an intricate cost keeping system, for that will depend entirely on the size of your plant, but what we do wish to emphasize is the necessity of some kind of cost record, especially in view of the present conditions.

WHY NOT TRY A SMALLER HOOK?

# MARKET DEVELOPMENTS

## PRICES EXPECTED TO REACH THEIR LOWEST LEVEL BY BEGINNING OF AUGUST

PITTSBURGH, June 30.—Demand for steel continues to be of practically [illegible] proportions. Considering conditions of the past month or two [illegible] that could be expected for the market would naturally grow duller as the midsummer season was approached. There is however, some debate in the trade as to whether the season of the year is the dominant factor. It is generally admitted that the steel market is always extremely dull in July, but in some quarters it is claimed that if the market wanted to revive it would not permit itself to be blocked by the calendar. However, much weight is given to two other factors, the stocks of steel and of finished wares in the hands of manufacturing consumers, and the feeling among buyers that steel prices are going to be lower.

Nearly all steel manufacturers place the former of these items in the forefront. They assert that buyers would not take hold no matter what prices were quoted, that they are engaged in liquidating their stocks. It is asserted, and with citation of actual cases of importance, that manufacturing consumers do not want to see lower steel prices, because they have no occasion to buy steel while they do want to liquidate their stocks of goods, and if steel prices were lower, their customers would expect lower prices on the manufactured goods, agricultural implements, tools, machinery, etc., so that a reduction in steel prices would be very unwelcome to many large buyers. That, of course, applies simply to the present. When buyers see their way clear to go ahead they will naturally prefer to see steel prices thoroughly liquidated.

### Steel Production.

Several large steel interests are closing their plants entirely at the end of this week, some for stated periods, say three to six weeks, others for indefinite periods. They are tired of losing money on a light operation, running say at 15 to 25 per cent. right along, or perhaps at 25 to 35 per cent. in alternate weeks, and prefer to take the smaller loss involved in being entirely idle and paying fixed charges out of surplus. Many small plants have been closed for months. Production of steel by the independents as a whole in the second half of June has been at nearer 15 per cent. than 20 per cent. of capacity, and the rate is likely to be 10 per cent. or less by the middle of July. As to the Steel Corporation there have been only occasional reports. Three weeks ago the Corporation was reported as operating at 30 per cent., while a week later it was up to 35 per cent. Possibly it is not doing over 25 per cent. at present. The Carnegie Steel Company has 14 of its 59 blast furnaces in operation. Its previous low record, late in 1914, was 16 furnaces active.

### Prices.

The whole sheet market is down by $5 a ton at least from the prices developed about the middle of April. Instead of there being a gradual sagging, there was a straight decline. The Republic Iron and Steel Company finding, as it stated, several independents quoting cut prices to some of its regular customers, openly announced a straight reduction of $5 a ton. Other manufacturers heard of this promptly, and immediately Youngstown Sheet & Tube Company, Brier Hill Steel Company and Bethlehem Steel Company announced similar reductions. The Steel Corporation waited three days and then began selling at the reduced prices, which are: Blue annealed, 2.85c; black, 3.75c; galvanized, 4.75c. Possibly these prices are being shaded slightly in some cases and certainly the market is not quotable higher in any case.

It was on May 31 that the Steel Corporation decided to meet independent price cutting on wire products, and reduced its prices $5 a ton. The action in sheets was taken more quickly than had been the action in wire. It is to be noted particularly that in each case the reduced prices are not announced as regular official prices of the corporation, but are referred to simply as prices at which the corporation subsidiaries are selling at the moment. The inference is that the corporation considers itself free, should occasion arise, to sell at lower prices than those mentioned without making formal announcement of the fact.

On other steel mill products, bars, shapes, plates, hoops, pipe, etc., there is more or less shading of April prices by some of the independents, without the Steel Corporation having modified its prices so far as known. Such action, however, is probably only a matter of days.

The opinion is that buying has reached, or will reach, such a low ebb that an increase will be forced, and the Steel Corporation will probably see to it that when buyers get in mood to take hold at all they will be quoted such prices as will encourage them. As many independent mills will be closed, prices can probably be set without much difficulty at levels that would entirely discourage any disposition to shade them, and this would naturally stimulate buyers to take hold. Thus the final shake-out in prices is likely to occur within the next few weeks, and probably by August 1. Prices may afterwards decline more, at intervals, in the event of its being possible to get costs down, but by far the greater part of the general price readjustment will be accomplished.

### Pig Iron and Coke.

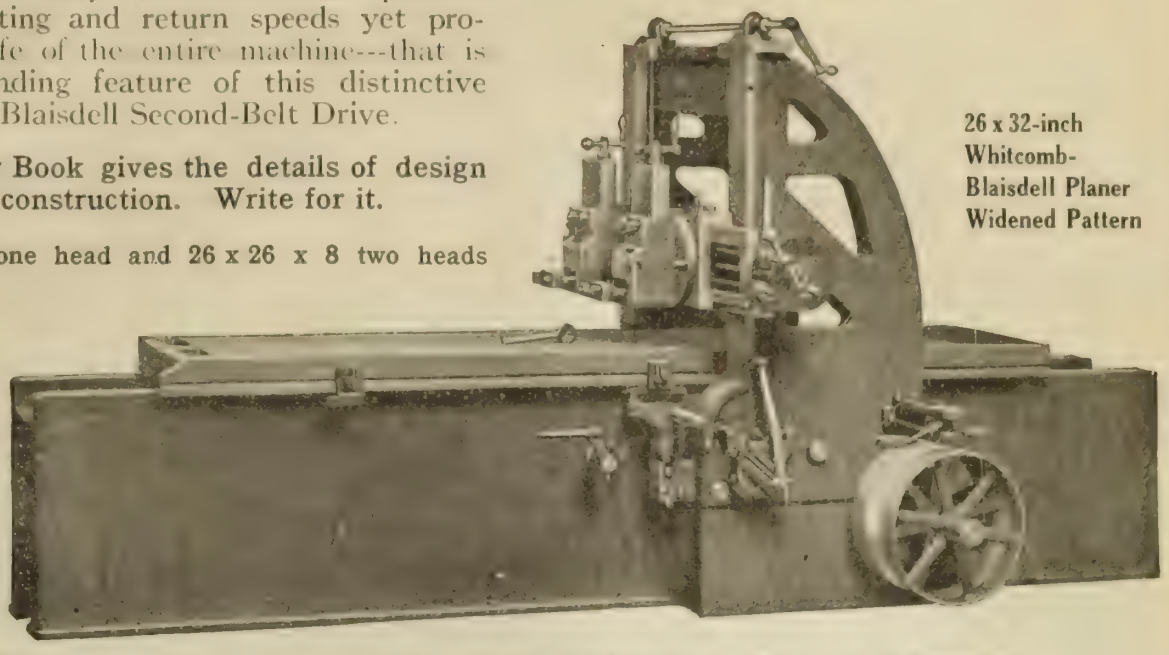
The local pig iron market has slid off 50 cents a ton on Bessemer and basic and $1 on foundry, making the market quotable at $22.50 for Bessemer, $20.50 for basic and $21.50 for foundry, f.o.b. valley furnaces, with $1.96 freight to Pittsburgh. The recent announcement of 1921 season prices for Lake Superior ore, at $1 reduction from 1920 prices, representing a return to the 1919 schedule, has not particularly affected the pig iron market, since a reduction of about this amount was discounted long ago. Indeed many if not the majority of furnaces wrote a dollar a ton off their ore inventories at the end of last year. Pig iron prices are made, not against the cost of producing the iron sold, nearly all the sales being out of furnace stocks, but against the probable cost of making iron when the furnaces have exhausted their stocks and have occasion to make more iron. The question is how long it will take to exhaust the stocks, for in time there will be reductions in freight rates, affecting the cost of assembling the raw materials at blast furnaces, and in all probability further wage reductions also.

Standard furnace coke has sold in single carload lots, to miscellaneous consumers, at $3 net to the consumer, brokers being allowed 10 or 15 cents margin. No sales to furnaces are reported. Considering the circumstances, it is thought probable that a furnace could buy, in fair sized lots, at about $2.75. Only a month ago furnaces thought they had made a great discovery when they found that if they offered a sufficiently attractive order they could probably buy at $3. Foundry coke is easier, and can be picked up at $4.25 for ordinary brands, some special brands being held at $4.50 and $4.75.

---

## CANADA NOT BUYING

**Table of exports from Britain and United States—British exports of iron and steel to Canada show marked decrease.**



According to the latest reports, the buying of British iron and steel by Canadian consumers has almost disappeared. American steel, however, continues to be shipped into Canada in large quantities. In 1912 and 1913 Canada was a rather good customer of Great Britain, but since the war the majority of this business has disappeared. Below is given a table, which shows clearly the change in the situation. The data shows the mon-

## THE A. R. WILLIAMS MACHINERY CO., LIMITED

**Halifax, St. John, Montreal, Winnipeg, Vancouver**

**If it's Machinery—Write "Williams"**

**64 Front Street West TORONTO**

thly exports of iron and steel in gross tons over certain periods.

| | —Tons per month— Gt. Britain to Canada | Un. States to Canada |
|---|---|---|
| 1912 | 12,000 | 82,400 |
| 1913 | 12,200 | 82,000 |
| 1919 | 1,000 | 43,400. |
| 1920* | 2,300 | 55,286 |

*May to December.

This data clearly points out that in 1919 British exports of iron and steel to Canada were only 1,000 tons per month, or one-twelfth what they were in 1912. American exports to Canada fell in 1919 to about one-half the pre-war rate, but recovered substantially in 1920. That Canadian steel production has not been a factor is evident from the fact that the 1920 output was not far from the 1913 output. It was a case of 1,108,939 tons in 1920, against 1,168,993 tons in 1913.

## OPPORTUNITY FOR CANADIANS

DISCUSSING his experience in trying to gather up some Canadian lines to represent in South America, a commission merchant made some pointed references to the attitude of Canadian firms toward export trade. Speaking to this paper he said: "There is a great opportunity for many Canadian lines at present. The exchange situation is favorable to Canada, and freight rates are lower than for some time, and there is a splendid connection too. There is a preference there for British goods. I have seen about thirty-five Canadian firms, and in not over half a dozen have I found that there is a keen interest in export business. One of the chief difficulties is that they do not want to quote a price outside of this country. They will quote me at their factory or on board a boat at Montreal, but if I asked for a price in some South American center, they would not give it to me, and until they are prepared to do so there is very little chance of them sending any of their goods to that country.

"Without any slight on this country, I can say that many of the firms I call on do not know anything about it. They know where it is, and that is about all. They have about as good a knowledge of Canada as the average Canadian has of South America. In order to do business successfully the Canadian must be prepared to put the best quality in his goods, for he is coming into competition with the rest of the world. He has to reduce his prices to the money of that country, and he has to quote right there in their own language, which for the most part is Spanish.

"Just imagine going from Canada to Buenos Aires, where I am established, 8,000 miles away, and telling a customer there that a certain article could be secured in Toronto, Canada for $500. Many of them would have to find out where Toronto, Canada was, as a starter. Then they would have to find out what the freight rates were in this country, and what schedule the firm had. They would have to learn the shipping rates on the ocean, and the rates of duty. I can tell the Canadian exporter, or would-be exporter, very plainly, that the South American is not going to that trouble because the goods are to be had from other countries, laid right down there with all prices and figures furnished in their own tongue and their own currency.

"Canada ought to be able to do well in that country, but firms here will have to show first that they are seriously desirous of getting the business there. Too many of them seem to think that the people down there are looking here for goods. They are not, but they would take Canadian goods in preference to German, and the exchange gives them an advantage over the United States prices."

## Pig Iron Markets

The operation of blast furnaces and steel works is slightly below the rate of last week. The Carnegie Steel Company has blown out another blast furnace and now has only 14 in operation out of 59. There is no longer any strict adherence to the prices announced by the Steel Corporation as effective April 13th. Reports have gone through the trade that a formal announcement of lower prices would be made July 1st. Market developments appear, however, to be making any such formality unnecessary. Producers are meeting competition as it develops.

Some producers or dealers on the Pittsburgh market have been induced to cut prices even for the small amount of business that is being placed, and this week Bessemer, basic, and mill iron are at least 50 cents per ton lower, while foundry is $1.00 lower. Demand for foundry iron is mostly for carload lots, and standard grades can be bought in this way at $21.50 Valley furnace for No. 2 foundry, with reports that $21 has been done.

Several sales at Chicago indicate another drop in the market of 50 cents a ton. Two 500-ton lots of Northern foundry were sold in Chicago and vicinity at $20.50 base furnace and a car or two lots have been moved at the same price.

The St. Paul Railroad purchased 700 tons of malleable and 100 tons of No. 1 foundry and is reported to have paid $20.50 base furnace. 1,000 tons of foundry iron was bought by a Wisconsin sanitary goods manufacturer. Although prices have declined without interruption since last fall, there are those who believe that a reaction may occur in the near future. Only two blast furnaces in this district are on merchant iron, one of them being a steel works stack. The blowing out of either one would tend to stiffen the market as stocks on furnace yards are not large.

On the Boston market a circular addressed to the New England trade offering a nameless iron in 1,000-ton lots, with a Buffalo freight rate, at $21.75 for either silicon 1.75 to 2.25 or silicon 2.75 to 3.25, August and September delivery, followed by an inquiry for 5,000 tons silicon 1.75 to 2.25 from the H. B. Smith Co., Westfield, Mass., which will be closed this week, brought out new low prices for this movement on Buffalo and eastern Pennsylvania. The circular offer was met by one of $21.50 for silicon 1.75 to 2.25 with 50 cents differentials by a northern furnace. Buffalo iron is reported as offered the Smith company at $20 shipping point, which with freight brings the delivered price to $25.16.

Buffalo reports that keen competition in Buffalo iron has developed with the effort of a mill interest to sell its pig iron ordinarily used in its steel activity. No startling orders however, have been booked, although one inquiry for 5,000 tons from New England is mentioned. The total inquiry of one maker for the week was 7,000 tons, much of it being for delivery for the latter part of the year, but conforming to the policy which has prevailed for some time, quotations are refused.

At Philadelphia so little business is being done that prices are stationary. A few weeks ago, Eastern furnaces determined to go no lower than $24 for No. 2 plain, $25 for No. 2X and $26 for No. 1X f.o.b. furnace, and they have apparently adhered to these quotations. There has been no temptation to cut on orders as they have been chiefly for carload lots

The Cincinnati market has been very quiet during the week. The largest reported sales were 320 tons to the National Cash Register Co., Dayton, Ohio, and two others of 200 and 100 tons respectively. Inquiries are confined mostly to carload lots. Chicago iron is being quoted into this district at $21 and much of the iron sold comes from that district.

At New York Buffalo iron is offered for sale as low as $20.75 furnace for No. 2X and even lower prices are rumored. The steel companies in Buffalo now seem to be more active than merchant furnaces in trying to sell iron. An inquiry for 1,000 tons of foundry iron for export to Japan has been received. It would be possible to import foreign pig iron at low prices, but there is no demand for it. Extreme dullness prevails.

## POINTS IN WEEK'S MARKETING NOTES

**There is a general dropping off in the production of steel, some mills closing indefinitely.**

**Manufacturers of steel implements and machinery do not want a general drop in the price of steel in the present market condition.**

**There has been a straight decline in the prices of sheets, and they are selling in some cases at lower than the quoted prices.**

**General price readjustment will have been completed by the beginning of August, though there may be isolated cases after that date.**

**The scrap market continues to be inactive, and where quotations are given they show further declines.**

**Pig iron prices are stationary in most cases, but there have been some price changes, always to a lower level.**

## Scrap Metal Markets

On the Pittsburgh market reports have been made by the local dealers to the effect that conditions are worse in the past week, consumers absolutely refusing to listen to offers of scrap even at very low prices, saying they do not need it and will not buy until general conditions are better. Most consumers of scrap in the Pittsburgh and Valley districts are not operating at more than 20 to 25 per cent. of capacity and say they have enough scrap to run them at this rate for two or three months.

At Chicago most grades of scrap have declined 50 cents a ton or more. Buying is being done very sparingly by consumers. 1,000 tons of heavy melting steel was recently purchased at $11 per gross ton, 100 tons of No. 1 wrought at $9.50 per net ton, and 150 tons of No. 1 bushelling at $8.75 per net ton.

Although quotations have not been lowered, the market for machinery cast appears softer. A nearby foundry bought 100 tons No. 1 at $18, delivered, the high price of the week. Stove plate is easier due to the withdrawal of a Norwood, Mass., buyer from the market.

At Philadelphia scrap is being offered by many dealers and there are few places to which it can be shipped. As a result prices show further declines. For delivery at consuming points in this district, No. 1 heavy melting steel is quoted at $11.00.

New York reports that one New York broker is paying $7.50 or heavy melting steel, though $7 is the more common price. Cast scrap has been the most active item, but the market as a whole is inactive and it is believed that the bottom has been reached.

At Cleveland the market shows no change, expecting that prices have further declined on most grades. Many dealers are making no effort to do business. About the only activity reported is the purchase of mixed borings and turnings and compressed steel in lots of 500 tons and under by the Weirton Steel Co. Car lots of heavy melting steel are being picked up by dealers at $10.

## Trade Gossip

The Scottish steel interests are greatly stirred by the fact that for the first time in history a United States concern has secured a valuable contract for the supply of steel axles to the state railways of India. Glasgow firms were thirty per cent. over the United States quotation for the contract. It is said that the value of the contract runs into six figures.

Tenders will be called shortly for erection of garage to cost $45,000 for A. Benoit, 96 Parc Georges Etienne Cartier, Montreal.

A studio and garage are being built by A. T. Van Buskirk, 95 Lawton Blvd., Toronto, at a cost of $15,000.

Walter McLean, Wallaceburg, Ontario, is contemplating the erection of a planing mill.

The Provincial Paper Mills Co., Ltd., 56 University Ave., Toronto, are planning the erection of a boiler house at Mille Roches, Ont.

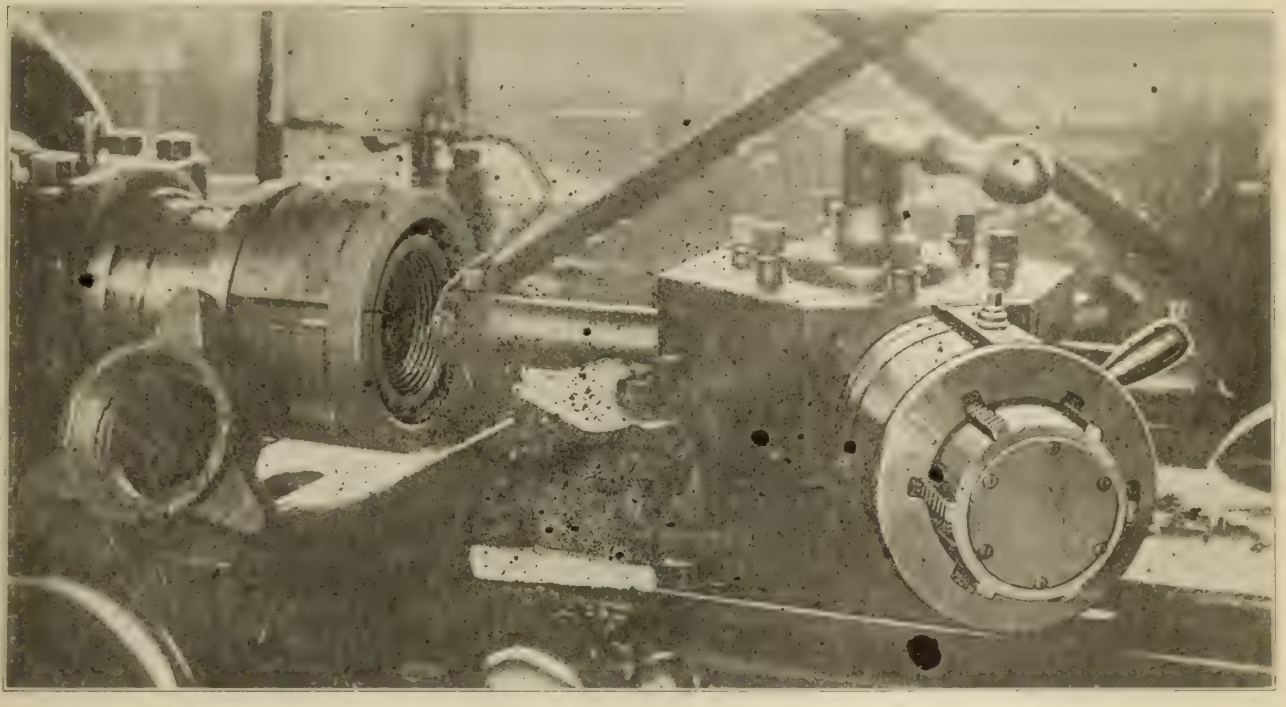
The Branson System of joist mould forms has been adopted for an office building costing $2,000,000 for the Canada Cement Co., 273 Craig St. W., Montreal. This building will be erected by the Canadian Steel Co., Ltd., 95 King St. E., Toronto, and 345 Union Ave., Montreal.

The Canadian Pacific Railway Company are contemplating the erection of station costing about $17,500 at Cardston, Alta.

Plans are being prepared by D. M. Morrison, architect for addition to car barns for London and Port Stanley Railway.

### ELECTRIC TRAMRAIL

The Cleveland Crane & Engineering Co. have recently developed what is known as an electric tramrail, which operates overhead like a crane yet is so flexible in character that it is said to be able to reach any desired corner of the plant.



This device is used for handling material in all lines of industry, and is said to be so simple in design that any mechanic can lay out, order and install the system, including switches, curves, turntables, etc.

Another important feature is its ability to connect one department or building with another that is on a higher level up to and including a grade of 12½%. For transferring to higher levels than this, or to a floor above or below, the tramrail may be installed on any freight elevator and elevated. Consequently the tramrail can pick up its load, carry and put it down anywhere from the basement to the roof, with but one handling.

NEW SHOPS, TENDERS AND CONTRACTS
PERSONAL AND TRADE NOTES

## STOPPAGE OF COAL PRODUCTION HAS RESTRICTED OUTPUT IN METAL INDUSTRIES

In an interview with H. M. Trade Commissioner at Toronto, Canadian Machinery received some interesting information on the Machinery and Engineering Trades in England.

The outstanding feature of the past month, says Mr. Field, "has been the stoppage of coal production, which has caused the restriction of output in practically all the metal industries. As regards iron and steel, in view of the definite relationship between the price of coal and the price of materials produced, the reduction in the market price obtainable for steel products has necessitated some reduction in the cost of coal if competition with foreign countries is to be met. In this connection it is rather curious to find that while the United Kingdom is apparently exporting steel abroad at competitive rates, she is still importing supplies. While the true reason for this is not very clear, it may be suggested that the British suppliers are prepared to make some temporary sacrifice in order to retain trade which may prove much more profitable under other circumstances. Whatever may be the outcome of the crisis, a reduction in the cost of coal will doubtless be effected, with consequent effect on the prices of iron and steel and machinery and engineering products generally.

**Machinery Exported.**

Although there has been a gradual reduction in the export of iron and steel in the raw state since July of last year, no similar movement is noticeable with regard to machinery. As a matter of fact, allowing for variations from month to month due to the nomal fluctuations of trade, there is a general tendency for the export of machinery to increase. It must be remembered, however, that the volume of machinery exported is still much below the figures for the years immediately preceding the war. The value of the exports of electrical machinery is comparatively steady, for during the last 18 months it has fluctuated between £600,000 and £900,000 per month. Vehicles, on the other hand, have undergone some violent fluctuations and although the tendency was to increase during 1920, a gradual decline has taken place during the current year.

There will undoubtedly be a period following the present industrial crisis in which a reduced volume of trade is done on account of the difficulty in obtaining supplies of raw materials which are dependent on coal for their production. Unemployment in the engineering trades is high, even relatively, although the amount of orders being executed does not, on the whole, decline. While a certain amount of this unemployment is inevitable, being caused by the inaction in the coal and iron trades, there are many directions in which increased trade could be done if orders were placed now. It seems that in some markets buyers are holding off because they expect further big reductions in cost of the finished articles. Economic considerations would not, however, appear to be altogether in support of this view.

The heavier machinery trades, with the sole exception of some of the textile machinery branches, are undoubtedly in want of as many orders as they can get for execution and delivery over an extended period. If buyers are afraid of being caught by a reduction in the cost of articles it is always possible to make an arrangement similar to the one in operation during the war by which the ultimate price varies in accordance with the costs of production. Such a clause, which undoubtedly protected the seller during the period of rising costs, would similarly operate for the protection of the buyer while prices are coming down. Orders should not therefore be postponed because of the possibility of a change in the purchasing power of money.

## WHY CANADA'S MILLS LOST RAIL ORDER

**Conditions Made it Impossible to Handle the Business in This Country.**

The recent announcement from Toronto that the Transportation Commission had placed an order for 4,000 tons of rails in the United States, because Canadian mills could not compete with the prices offered across the border carried a rather unpleasant suggestion in industrial circles here. Inquiries made by The Corporation as to why it had not been able to "land" such an order for a Canadian plant, placed the inference in a much more favorable light.

In the first place the first order called for a 7-inch girder rail that has never been made in Canada before, much different from the ordinary 100-pound T rail used for steam roads. Then an alternative order called for T rails but the drilling was different and a length of 62 fet was essential as compared with the 32-foot length of the ordinary rail. This would have required new equipment in the form of hot tables, etc., and at the time the plants were starting up on an order from the Dominion Government that called for delivery on a special date. It would have been difficult if not impossible to get permission to suspend the Government order so as to complete the Toronto Commission's order.

## GERMAN GOODS FIND READY SALE

**Germany is Out to Regain Her Commercial Position. Average Daily Wage in Berlin is $1.20.**

"Germany is out to regain, on a great scale, her commercial position in the world, and at the pace she has begun, she has a good chance of achieving her objective." This briefly, is the opinion of Mr. Penton, secretary of the American Pig Iron Association, and president of the Penton Publishing Co., Cleveland, Ohio.

Mr. Penton has just returned to London, England, after investigating commercial conditions in Germany and France, and previous to this he studied conditions in England. He names the German industrial magnate. Hugo Stinnes, as the leading figure in the German World trade offensive.

"Herr Stinnes is, in the realm of commerce, what former Kaiser William was in international politics," says Mr. Penton. "The Kaiser dreamed of the political conquest of France and England, and the East. Stinnes has his dreams, too, but they are not political. Stinnes sees Germany capturing every market in the world, sees German ships in every port in the world, German banks in every business centre in the world, and Germans as pioneers in developing new territory which possesses commercial possibilities."

**Indemnity Will Be Paid.**

Regarding the payment of the indemnity by the Germans, Mr. Penton says that every industrial leader with whom he talked, including some of the biggest in Germany, plainly expressed the realization that the indemnity must be paid.

"And Germany is, I believe, going ahead to pay it," Mr. Penton continued. "For instance, Germany is going to float the biggest bond issues in the history of the world, and to institute by degrees the stiffest taxation in the world for this purpose. She expects to pay the indemnity and to build up her prosperity at the same time."

**Tells the Story.**

The figures Mr. Penton gives of the average daily wage in Europe are highly significant. In Germany it is $1.20; in Belgium, $1.60; in France, $1.70, and in England, $3.50. That goes a long way in telling the story why Mr. Penton saw German tools and machinery being bought in France in competition against French products. England, America, and almost every other country are buying some steel in Germany to-day.

"But it is really eastward, to Russia, that Germany is turning her eyes for trade. She is out to capture Russia's huge orders for manufacturers when that country begins buying again, and

## NEW PROVISION Re MARKING GOODS

At the session of Parliament, which closed recently, a new statutory provision was adopted which will require imported goods to be marked, where practicable, with the name of the country of origin. This new provision becomes effective on goods entering the country on and after Oct. 1st., 1921. Following are the particulars of the new provision.

That all goods imported into Canada which are capable of being marked, stamped, branded or labelled, without injury, shall be marked, stamped, branded, or labelled in legible English or French words, in a conspicuous place that shall not be covered or obscured by any subsequent attachments or arrangements, so as to indicate the country of origin. Said marking, stamping, branding, or labelling shall be as nearly indelible and permanent as the nature of the goods will permit.

Provided that all goods imported into Canada after the date of the coming into force of this section which do not comply with the foregoing requirements shall be subject to an additional duty of ten per centum ad valorem to be levied on the value for duty purposes and in addition such goods shall not be released from Customs possession until they have been so marked, stamped, branded or labelled under Customs supervision at the expense of the importer.

Provided further that if any person shall violate any of the provisions relating to the marking, stamping, branding, or labelling of any imported goods, or shall deface, destroy, remove, alter, or obliterate any such marks, stamps, brands, or labels, with intent to conceal the information given by or contained in such marks, stamps, brands, or labels, he shall be liable on summary conviction to a penalty not exceeding one thousand dollars, or to imprisonment not exceeding one year, or to both fine and imprisonment. The Minister of Customs and Inland Revenue may make such regulations as are deemed necessary for carrying out the provisions of this section and for the enforcement thereof.

It is possible that the regulations made by the Customs dept. for the purpose of carrying out the provisions of this new legislation may have to be added to as experience in its administration develops, but in any case the Customs dept. will soon be settling how the regulations will apply.

## MINING EXPOSITION ON A LARGE SCALE

The National Exposition of Mines and Mining Equipment to be held in Chicago, October 17-22 in conjunction with the 24th annual convention of The American Mining Congress, is said to be the first national exposition devoted exclusively to telling the story of the mining industries.

At the exposition each of the basic mining enterprises, iron, copper, coal, gold, silver, lead, zinc and many others will be represented by an exhibit. The salient facts in regard to these industries will be presented by means of maps, graphic charts, ore exhibits and the story of their growth will be thrown upon the screen for the benefit of visitors.

The United States Bureau of Mines is preparing a special series of motion picture films to illustrate the development of these industries and the methods now used.

**Importance of Mining Industries.**

Except when the glamor of new discoveries focuses public attention upon some phase of the mining industry, little attention is ordinarily paid to the hard work and difficult problems which confront the mine operator. Few people realize that the mining industries furnish sixty per cent. of the total volume of freight carried by the United States railroad systems or that the value of the mining products produced aggregate nearly three billion dollars annually, that the mining industry gives employment to over one million men. The mining industry is playing an important role in the new export trade development. In 1920 the exports of mine products including coal, copper and other metals, was valued at approximately six hundred million.

## BRITISH LETTER RATE IS DOUBLED

The British letter rate to Canada has been doubled, being now 4c. instead of 2c. There was a proposal to increase the postal rates on business and trade and technical newspapers sent to Canada but the Government after looking into the matter decided not to do so and when an announcement to that effect was made in the British House of Commons on June 9th it was, according to cables appearing in Canadian newspapers, greeted with tremendous applause. The Postmaster-General pointed out that even the leading daily newspapers in Great Britain opposed any increase of rates on technical and trade newspapers because it would hamper British spirit and enterprise overseas as compared with the United States and Germany and would retard the recovery of British export trade.

Sir Geo. Foster said that the British Trade Commission, of which he was a member, had found, chiefly on the evidence submitted to them in Australia, that the reason German manufacturers had secured such a powerful and increasing hold on the Australian market was their persistency in salesmanship. Sir George did not get the whole story, or, if he did, he failed to apply it. That salesmanship was spoken and written. The way for German salesmen was prepared in advance. Their advertising in the business newspapers—printed in English sometimes—preceded their salesmen for two or three years and it came to the desks of their customers weekly or monthly to supplement the calls of their salesmen—to work for them while their salesmen were not there. Germans were much better and more persistent advertisers than British in the Canadian field before the war.

### CROSS INDEXING MECHANICAL INFORMATION.

(By F. M.)

A very convenient method of indexing miscellaneous information, such as is usually accumulated from catalogues, notes and magazines, is shown by the accompanying chart. This chart may be used where the information indexed is placed in regular letter files, cabinets or most anywhere that a letter of numbered system is used.

Referring to the chart it will be noticed from the title that this index refers to "File number 1," from January 1918, to a date which is to be filled in when a new index sheet and additional file is developed. Below the title in the diagonal spaces are major titles such as Lathe, Milling, Planing, etc. In the column at the extreme left are a number of sub-titles. Intersecting lines running from both of these titles form spaces in which letter or numbers are placed and reading down from one column along the top and across from a column on the side; by noting the letter in the space which they form where they intersect, it is apparent that the subject matter so designated is filed under that letter or numeral.

For example, we will presume that it is desired to look up information that has been accumulated under "Advertising Forms." Looking along the top we find the word "Forms," and glancing down the left hand column we find "Advertise," while in the square where the two intersect, is the letter "V." One would therefore look into the file "V" for the information desired; likewise if it was desired to find information in regard to drilling machines, one would look along the top to the word drilling; along the left to the word machines, and at the intersection of the two is the letter K indicating the file to be looked up,

A chart of this nature can be easily compiled to suit individual requirements and may be more or less extensive. It can be pasted on a card and makes a very handy visible index,

### CHINA DESIRES TRADE WITH CANADA.

Writing to the Chambers of Commerce in Canada, C. C. Nieh, president of the Chinese General Chamber of Commerce at Shanghai, has the following to say:—

"Within the last decade the foreign trade of China has been doubled in spite of the revolutions and other internal disturbances. None can tell how many times greater her trade will expand during the next ten years. Her ability to supply the world markets with agricultural products and minerals is manifold; her capacity of consumption for foreign goods is multiplied by the rapid growth of modern industries. Many observers believe that China is on the verge of a great industrial revolution."

"Reviewing China's foreign trade in the past we regret to see that Canada has not taken as large a share as might be expected from her excellent transportation system with Chinese ports. This, we think, is largely due to the fact that the tremendous trade possibilities in China have not been sufficiently well-known to your business public. The Chinese General Chamber of Commerce of Shanghai, an association of some 400 representative merchants and manufacturers of Shanghai, desires to see more trade between Canada and China, and take this opportunity to express to the Canadian merchants and manufacturers its sincere wishes for closer relationship, which will, no doubt, result in mutual advantage and satisfaction, commercial and otherwise."

Here is an invitation that Canadian merchants generally would do well to look into.

# SKF

## SKF Engineers Gather the Mechanical News of the World

They come to your plant with a knowledge gained not only in Canadian plants, but in American, British, Swedish, Swiss, French, Japanese and many other industrial plants.

If your mechanical problems have been solved before in any part of the world, **SKF** engineers can tell you how it was done.

It is their mission in life to help manufacturers get:

—increased production
—lower power and labor costs
—lower repair costs
—improved products.

Consult Canadian **SKF** Engineers about any problem in your plant. Their services cost you nothing.

# TORONTO FIRM SECURES CONTRACT

**Preliminaries of Detroit-Windsor Bridge Completed. Detail Design is Started—Particulars of Proposals.**

Announcement has been made by Chas. Evan Fowler, that the preliminary work on the Detroit-Windsor Bridge has been completed.

The work on the detail designs of the bridge will be begun at once. The investigations for this purpose must of necessity be very extensive, as the structure as now located and planned will be the longest and heaviest span in the world. The very great need for the highway portion of the structure, makes it advisable to proceed with the traffic bridge and complete that deck before adding the railway portion. The span will be 1,905 feet, and there will be two roadways, each 28 feet in width, paved with concrete; two 7 feet sidewalks also paved with concrete; and the two trolley tracks over which it is proposed to arrange for the operation alternately of Detroit and Windsor street cars, thus making it possible to give transfers to all parts of both cities. The current for the operation has been promised on a reasonable basis by the Hydro as soon as the new Niagara plant is completed.

### Foundations.

The foundations for the bridge will be sunk to bedrock at a depth of 100 feet by the pneumatic process, and this work will be done by the Bridge Company. The contract for the steel-work will be made as soon as the plans are fully developed, but arrangements have already been consummated whereby the wire for the cables will be furnished by the Roebling Company, who made the cables for the three great suspension bridges over the East River at New York City. These cables will consist of approximately 10,000 separate wires in each cable, with ultimate strength of 240,000 pounds per square inch. They will be placed by stringing one wire at a time until all eight cables are completed and wrapped with wire, the whole process requiring about eight months.

The contract has already been signed between the American Transit Company, which has the authority from Congress to span the river, and the Canadian Transit Company as chartered by parliament, for joint action in financing and building the bridge. The joint board of directors of eleven members will be elected in August, and the proposition of the R. T. Scott Company of Toronto, will then be accepted for the sale of the bonds for the full amount required for the construction. The proposition of this company will meet with the approval of those interested in the bridge, as it provides for a structure built and financed solely for the public benefit without profits accruing to the promoters, further than a reasonable compensation to the directors for their four to five years tenure of office.

### Electric Locomotives.

The plans as prepared by the chief engineer, who will also act as chairman of the board of consulting engineers, will be approved by a board consisting of George H. Pegram, chief engineer of the Interborough Rapid Transit Company of New York City; Col. C. N. Monsarrat, of Montreal, formerly chairman of the board of engineers of the great Quebec bridge; Pro. Wm. H. Burr, of New York, one of the board of engineers on the Panama Canal, and also for the East River bridges; Prof. C. R. Young of the University of Toronto.

The railway deck is planned to have four tracks, with the approaches on 1½ per cent. grades, and connect with the Essex Terminal Railway in Windsor, thus affording access to the Grand Trunk, Pere Marquette and Canadian Pacific Railways; and on the American side with all the railways entering Detroit. The operation would be by electric locomotives weighing about 120 tons each, which would ordinarily haul from 30 to 40 freight cars, but in emergency about 50 cars. This would provide for the increase in future years up to about five million cars per annum.

---

# YOUNG MEN HAVE IDEAL OPPORTUNITY

Speaking before the graduating class of the Stevens Institute of Technology in Hoboken, the other day, Chas. M. Schwab, chairman of the board of the Bethlehem Steel Corporation, gave to the young men present some advice and encouragement that is well worth passing on.

"What would I not give—whatever of fame or wealth has come to me in life," said Mr. Schwab, "to be as one of you boys here to-day with the opportunity to live and develop in the years to come! People sometimes ask if a young man has as good opportunities as he used to have. I am not a prophet, but I firmly believe we are only now standing upon the threshold of an era which is to mark the greatest scientific and industrial advancement in the history of the world. And it is to young men like you will come the priceless opportunity to make yourselves invaluable in the rebuilding of civilization.

"I am not going to talk to you upon technical topics," he continued. "For there is something more in the world than technical engineering. I have noticed that men who have grown great in these constructive lines of effort have not relied too much upon their technical knowledge. There is one branch of engineering I wish to speak about—human engineering, the ability to collect from those with whom you come in contact the benefits of such knowledge and experience as they have accumulated.

"You will find, as I have found every day of my life, that there is nobody from whom you may not be able to learn something of value. When you go from here into the shop you will find you know some things the man in the shop does not know and probably that he knows many things that you didn't know. Keep your minds receptively open. Do not look down on the man in the shop. Do not treat him patronizingly. Try to win his regard. The best things I have learned often have come to me from the working man, ideas that have come to me from the man in the shop or the shop foreman and then have been developed perhaps by such technical knowledge as you learn here."

### IMPROVISED CASTING PATTERN.

By CHAS. E. HALL.

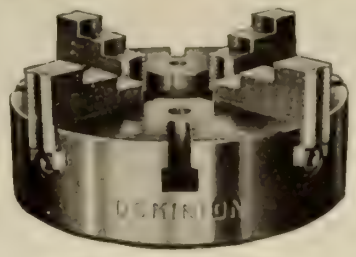
A jewelry manufacturing concern, having secured an order for a bishop's crozier in sterling silver 6 ft. 6in. high, which was to be made according to a specified design, and such articles not being in every-day demand, it was essential that the cost be kept as low as possible, particularly on account of the difficulty of estimating on a first order of this nature.

The crook section was about 18" over all, and a gradual taper from 1" in diameter at the large end, to ⅜" in diameter at the other. A local pattern-maker quoted $35.00 for a core box and pattern, a price which the estimate made prohibitive. It was decided to make the pattern in the shop, and the method adopted may help out in other fields.

A tracing was made of the outline of the crook from the drawing, with a center line drawn the entire length, as in Fig 1., and primed down on the drawing board. A piece of wire was bent to conform to the center line to obtain the exact length, and a straight tapered wooden pattern turned up, the length of the wire, ⅞" thick at the large, and ¼" at the small end. In other words, less two thicknesses of metal or ⅛". A piece of 2" pipe of suitable length, was used as a moulding box, and the wooden pattern rammed up in sand, and a lead cast taken. This was filed smooth and bent to conform to the shape of the crook, and lightly coated with bees-wax. Strips of paper were wrapped round the lead core; shellaced, and allowed to set. There happened to be on hand a few bolts of damaged silk ribbon about ½" wide which came in very handy.

This was then wound on, shellacing each layer, till it was built up to the diameter of the crook. Two or three layers of paper were now added, to allow for filing and polishing, and when perfectly hard, was cut into two halves with a sharp knife—as shown at Fig. 2, and lifted off the lead core, the bees-wax preventing it from sticking. Using these as patterns, the two halves were cast in silver, filed flat on the edges, hard soldered together, and the crook filed up.

By this method the whole job of making the pattern only occupied about three hours, which was a decided saving on a pattern and core box at $35.00.



---

### HAS QUADRUPLED IN CANADIAN MINES SINCE 1916.

A recent report issued by the Imperial Mineral Resources bureau shows that the output of zinc from Canadian mines has more than quadrupled since 1916.

Previous to that year the output was negligible and the bureau did not keep a record of it. According to figures given in the report, the output from Canadian mines in 1916 was 2,655. In 1919 production had jumped to 11,005 tons.

Reporting on the deposits within the empire the report attached special significance to the zinc-lead-silver ores in British Columbia and to the development of proper handling facilities at Trail, B.C. Much still remains to be done before the British empire can be considered self-supporting in the matter of smelter production, the report stated. In this connection the construction of a successful electrolytic-treatment plant at Trail, with a capacity of 15,000 tons of spelter a year, was given as a hopeful indication.

DOMINION CHUCKS

STEEL OR CAST-IRON BODY
BUILT FOR HEAVY DUTY

All Screws Are Reversible

SCREWS are made of the best grade steel. Both ends are broached and are heat treated after machining. They are reversible, so that either end may be used, are large enough in diameter to stand the torsional strains applied by operator when setting up his work. They are made to give the best service—and may be depended upon to stand up under the hardest usage.

SMOOTH-ON ELASTIC CEMENT No3

Leaks Run Into Dollars

Stopping leaks in flanges and screw-thread joints is the easiest thing Smooth-On Iron Cement No. 3 does. Cracks in pipes, boilers, cylinders, valves—almost any power plant part—can be repaired easily and quickly.

Send for our new Smooth-On Instruction Book No. 18. It illustrates and describes many repairs actually made with Smooth-On Iron Cement. Most of these repairs being described by the Engineers who did the work. Many repairs are unusual, but most of the repairs might be needed in your power plant or boiler room any day.

May we send you a copy of Smooth-On Instruction Book No. 18? It's free, of course.

## WILLIAMS' SUPERIOR DROP FORGED HAMMERS

**Are dependable tools because:—**

Their heads, drop-forged from a special grade of tough steel, carefully hardened and tempered, neither crack, chip nor splinter. They are fastened most securely and solidly to the handles—can't work loose—can't fly off.

Their handles are made of the best grade of clear, straight-grained hickory, flared at the grip to prevent hand-slip.

The weight and length of each tool are properly proportioned to give perfect balance, and, hence, increased striking power.

Williams' quality Hammers of all kinds and sizes. Catalog on request.

## DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. This necessarily widened the scope of our Directory, but it would be impracticable to list all the lines handled by all the dealers. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

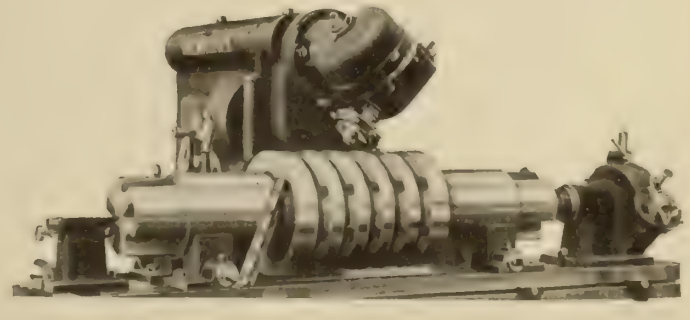
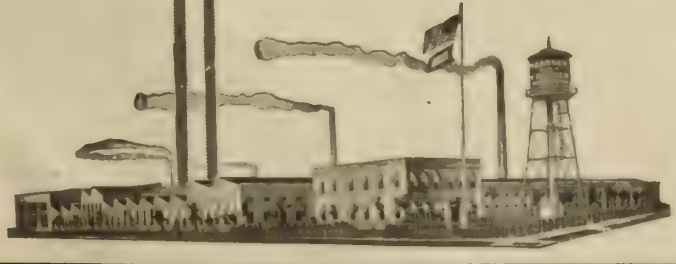
# MILWAUKEE MILLING MACHINES



## Efficient on Light and Heavy Milling



Heavy milling jobs are not unknown to Milwaukee Universal Milling Machines, while delicate and intricate ones are efficiently performed with little effort.

Both light and heavy milling operations are handled with such smoothness and accuracy that the finest results are obtained. Because Milwaukee Universal Milling Machines perform such a wide variety of work, they are particularly well adapted for the tool-room.

The jobs shown in the two illustrations are representative of "Milwaukee" adaptability. The upper illustration shows a jig being bored with a fly cutter. The lower illustrates the milling of a chilled roll with the use of a Universal Milling Attachment.

***Asphalt***—The asphalt compound is used for the first coating because scientific experiments over a long period of years have demonstrated that it forms the best protector of steel against corrosion.

***Asbestos***—Asbestos felt also completely covers the steel and is firmly bonded to the asphalt. Because of its fibrous-rock formation asbestos is indestructible. It cannot rot or decay. Acids and alkalies do not affect it.

***Waterproofing***—The third coating is a tough envelope of weather resisting and chemically inert compound. It forms the first protective layer which reinforces and multiplies the durability of the finished product.

# A Sure Building Investment

You can buy investment value or costly depreciation. You can buy Robertson Process Metal or ordinary metal. One is protected, the other is not. It is this protection that makes the difference between long profitable life and quick depreciation in your factory buildings.

The Robertson Process of protection is a three-coat process (1) Asphalt (2) Asbestos (3) Waterproofing, which completely encases the steel core. It covers both surfaces and edges. It forms a sure, rust and corrosion-resisting shield. The core of specially annealed steel is thoroughly cleaned. It is next immersed in a special, long-lived asphalt compound. This asphalt coating is then protected by an insulating cover of long-fibred Canadian asbestos felt previously saturated with refined asphalt. This is followed by a tough moisture-repellent coat of waterproofing. By powerful machinery the coatings are moulded into a strong and elastic protective shield.

These operations are illustrated by the process sample which shows the successive steps of protection. A sample of Robertson Process Metal will be sent upon request. Write today and let us send you practical building literature that will bring home to you the advantage you personally can gain through the use of Robertson Process Metal for roofs, siding, trim, gutters, etc.
